#### Abstract

It is proved that the classical Laplace transform is a continuous valuation which is positively $\mathrm{GL}(n)$ covariant and logarithmic translation covariant. Conversely, these properties turn out to be sufficient to characterize this transform.

## 1 Introduction

Let $f:[0, \infty) \rightarrow \mathbb{R}$ be a measurable function. The Laplace transform of $f$ is given by

$$
\mathcal{L} f(s)=\int_{0}^{\infty} e^{-s t} f(t) d t, \quad s \in \mathbb{R}
$$

whenever the integral converges. In the 18th century, Euler first considered this transform to solve second-order linear ordinary differential equations with constant coefficients. One hundred years later, Petzval and Spitzer named this transform after Laplace. Doetsch initiated systematic investigations in 1920s. The Laplace transform now is widely used for

[^0]solving ordinary and partial differential equations. Therefore, it is a useful tool not only for mathematicians but also for physicists and engineers (see, for example, [7]).

The Laplace transform has been generalized to the multidimensional setting in order to solve ordinary and partial differential equations in boundary value problems of several variables (see, for example, [6]). Let $f$ be a compactly supported function that belongs to $L^{1}\left(\mathbb{R}^{n}\right)$. The multidimensional Laplace transform of $f$ is defined as

$$
\mathcal{L} f(x)=\int_{\mathbb{R}^{n}} f(y) e^{-x \cdot y} d y, \quad x \in \mathbb{R}^{n}
$$

The Laplace transform is also considered on $\mathcal{K}_{n}^{n}$, the set of $n$ dimensional convex bodies (i.e., compact convex sets) in $\mathbb{R}^{n}$. The Laplace transform of $K \in \mathcal{K}_{n}^{n}$ is defined by

$$
\mathcal{L} K(x)=\mathcal{L}\left(\mathbb{1}_{K}\right)(x)=\int_{K} e^{-x \cdot y} d y, \quad x \in \mathbb{R}^{n}
$$

where $\mathbb{1}_{K}$ is the indicator function of $K$. Making use of the logarithmic version of this transform, Klartag [19] improved Bourgain's esimate on the slicing problem (or hyperplane conjecture), which is one of the main open problems in the asymptotic theory of convex bodies. It asks whether every convex body of volume 1 has a hyperplane section through the origin whose volume is greater than a universal constant (see also [20] for more information).

Noticing that both Laplace transforms are valuations, we aim at a deeper understanding on these classical integral transforms. A function $z$ defined on a lattice ( $\Gamma, \vee, \wedge$ ) and taking values in an abelian semigroup is called a valuation if

$$
\begin{equation*}
z(f \vee g)+z(f \wedge g)=z(f)+z(g) \tag{1.1}
\end{equation*}
$$

for all $f, g \in \Gamma$. A function $z$ defined on some subset $\Gamma_{0}$ of $\Gamma$ is called a valuation on $\Gamma_{0}$ if (1.1) holds whenever $f, g, f \vee g, f \wedge g \in \Gamma_{0}$. Valuations were a key ingredient in Dehn's solution of Hilbert's Third Problem in 1901. They are closely related to dissections and lie at the very heart of geometry. Here, valuations were considered on the space of convex bodies in $\mathbb{R}^{n}$, denoted by $\mathcal{K}^{n}$. Perhaps the most famous result is Hadwiger's characterization theorem which classifies all continuous and rigid motion invariant real valued valuations on $\mathcal{K}^{n}$. Klain [15] provided a shorter proof of this beautiful result based on the following characterization of the volume.

Theorem 1.1 ( $[14,15])$. Suppose $\mu$ is a continuous rigid motion invariant and simple valuation on $\mathcal{K}^{n}$. Then there exists $c \in \mathbb{R}$ such that $\mu(K)=c V_{n}(K)$, for all $K \in \mathcal{K}^{n}$. Here, $V_{n}$ is the $n$ dimensional volume.

Other important later contributions can be found in $[14,18,34,35]$. For more recent results, we refer to $[1,2,8-13,16,17,22,24-26,30,32,37,38,40-42,46]$.

With the first result of this paper, we characterize the Laplace transform on convex bodies.

Theorem 1.2. A map $Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, positively $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation if and only if there exists a constant $c \in \mathbb{R}$ such that

$$
Z K=c \mathcal{L} K
$$

for every $K \in \mathcal{K}_{n}^{n}$.
Throughout this paper, without further remark, we briefly write positively GL( $n$ ) covariant as GL $(n)$ covariant; see Section 2 for definitions of GL $(n)$ covariance and logarithmic translation covariance. We call $Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ continuous if for every $x \in \mathbb{R}^{n}$, we have $Z K_{i}(x) \rightarrow Z K(x)$ whenever $K_{i} \rightarrow K$ with respected to the Hausdorff metric, where $K_{i}, K \in \mathcal{K}_{n}^{n}$.

Notice that $\mathcal{L} K(0)=V_{n}(K)$ holds for all $K \in \mathcal{K}_{n}^{n}$. Thus, this characterization is a generalization of Theorem 1.1.

Valuations are also considered on spaces of real valued functions. Here, we take the pointwise maximum and minimum as the join and meet, respectively. Since the indicator functions of convex bodies provide a one-to-one correspondence with convex bodies, valuations on function spaces are generalizations of valuations on convex bodies. Valuations on function spaces have been studied since 2010. Tsang [43] characterized real valued valuations on $L^{p}$-spaces. Kone [21] generalized this characterization to Orlicz spaces. As for valuations on Sobolev spaces, Ludwig [27,28] characterized the Fisher information matrix and the Lutwak-Yang-Zhang body. Other recent and interesting characterizations can be found in [3-5, 29, 33, 36, 44, 45].

With the second result of this paper, we characterize the Laplace transform on functions based on Theorem 1.2 and the natural connection between indicator functions and convex bodies. Let $L_{c}^{1}\left(\mathbb{R}^{n}\right)$ denote the space of compactly supported functions that belong to $L^{1}\left(\mathbb{R}^{n}\right)$. We call $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ continuous if for every $x \in \mathbb{R}^{n}$, we have $z\left(f_{i}\right)(x) \rightarrow z(f)(x)$ whenever $f_{i} \rightarrow f$ in $L^{1}\left(\mathbb{R}^{n}\right)$.

Theorem 1.3. A map $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, positively $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation if and only if there exists a continuous function $h$ on $\mathbb{R}$ with the properties that

$$
\begin{equation*}
h(0)=0 \tag{1.2}
\end{equation*}
$$

and that there exists a constant $\gamma \geq 0$ that

$$
\begin{equation*}
|h(\alpha)| \leq \gamma|\alpha| \tag{1.3}
\end{equation*}
$$

for all $\alpha \in \mathbb{R}$, such that

$$
z(f)=\mathcal{L}(h \circ f)
$$

for every $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$.

If we further assume that $z$ is 1-homogeneous, that is, $z(s f)=s z(f)$ for all $s \in \mathbb{R}$ and $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$, then we obtain the Laplace transform.

Corollary 1.4. A map $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, 1-homogeneous, positively $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation if and only if there exists a constant $c \in \mathbb{R}$ such that

$$
z(f)=c \mathcal{L} f
$$

for every $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$.

## 2 Preliminaries and Notation

Our setting is the $n$-dimensional Euclidean space $\mathbb{R}^{n}$ with the standard basis $\left\{e_{1}, \ldots, e_{n}\right\}$, where $n \geq 1$. The convex hull of a set $A$ is denoted by $[A]$ and the convex hull of a set $A$ and a point $x \in \mathbb{R}^{n}$ will be briefly written as $[A, x]$ instead of $[A,\{x\}]$. A hyperplane is an $n-1$ dimensional affine space in $\mathbb{R}^{n}$. The unit cube $C^{n}=\sum_{1 \leq i \leq n}\left[o, e_{i}\right]$ and the standard simplex $T^{n}=\left[o, e_{1}, \ldots, e_{n}\right]$ are two important convex bodies in this paper.

The Hausdorff distance of $K, L \in \mathcal{K}^{n}$ is

$$
d(K, L)=\inf \{\varepsilon>0: K \subset L+\varepsilon B, \quad L \subset K+\varepsilon B\} .
$$

The norm on the space $L_{c}^{1}\left(\mathbb{R}^{n}\right)$ is the ordinary $L^{1}$ norm which is denoted by $\|\cdot\|$.
A map $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is called $\mathrm{GL}(n)$ covariant if

$$
\begin{equation*}
z\left(f \circ \phi^{-1}\right)(x)=|\operatorname{det} \phi| z(f)\left(\phi^{t} x\right) \tag{2.1}
\end{equation*}
$$

for all $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right), \phi \in \mathrm{GL}(n)$ and $x \in \mathbb{R}^{n}$. In this paper, we actually deal with positive $\mathrm{GL}(n)$ covariance, that is (2.1) is supposed to hold for all $\phi \in \mathrm{GL}(n)$ that have positive determinant. Also, a map $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is called logarithmic translation covariant if

$$
z(f(\cdot-t))(x)=e^{-x \cdot t} z(f)(x)
$$

for all $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$ and $t, x \in \mathbb{R}^{n}$. This definition is motivated by the relation

$$
\log \mathcal{L}(f(\cdot-t))(x)=-x \cdot t+\log \mathcal{L} f(x)
$$

(see Theorem 3.1).
A map $Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is called $\mathrm{GL}(n)$ covariant if

$$
Z(\phi K)(x)=|\operatorname{det} \phi| Z K\left(\phi^{t} x\right)
$$

for all $K \in \mathcal{K}_{n}^{n}, \phi \in \mathrm{GL}(n)$ and $x \in \mathbb{R}^{n}$. Also, a map $z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is called logarithmic translation covariant if

$$
Z(K+t)(x)=e^{-t \cdot x} Z K(x)
$$

for all $K \in \mathcal{K}_{n}^{n}$ and $t, x \in \mathbb{R}^{n}$. Again, it is motivated by the relation

$$
\log \mathcal{L}(K+t)(x)=-t \cdot x+\log \mathcal{L} K(x)
$$

(see Theorem 3.3). If a valuation vanishes on lower dimensional convex bodies, we call it simple.

As we will see in Lemma 3.2, if $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is continuous, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant, then $Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ defined by $Z K=z\left(\mathbb{1}_{K}\right)$ is also continuous, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant, respectively.

For the constant zero function, if $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is $\mathrm{GL}(n)$ covariant and logarithmic translation covariant, then

$$
\begin{equation*}
z(0) \equiv 0 \tag{2.2}
\end{equation*}
$$

Indeed, $z(0)\left(\phi^{t} x\right)=z(0)(x)$ for any $\phi \in \operatorname{GL}(n)$. Let $x=e_{1}$. We have that $z(0)$ is a constant function on $\mathbb{R}^{n} \backslash\{0\}$. The continuity of the function $z(0)$ now gives that $z(0) \equiv c$ on $\mathbb{R}^{n}$ for a constant $c \in \mathbb{R}$. Since $z$ is also logarithmic translation covariant, $z(0)(x)=e^{-t \cdot x} z(0)(x)$ for any $x, t \in \mathbb{R}^{n}$. Hence $z(0) \equiv 0$.

## 3 Laplace transforms

In this section, we study some properties of Laplace transforms.
Theorem 3.1. Let $h$ be a continuous function on $\mathbb{R}$ satisfying (1.2) and (1.3). If a map $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ satisfies

$$
z(f)(x)=\int_{\mathbb{R}^{n}}(h \circ f)(y) e^{-x \cdot y} d y
$$

for every $x \in \mathbb{R}^{n}$ and $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$, then $z$ is a continuous, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation.

In particular, if $h(\alpha)=\alpha$ for all $\alpha \in \mathbb{R}$, the Laplace transform $\mathcal{L}$ on $L_{c}^{1}\left(\mathbb{R}^{n}\right)$ is a continuous, GL( $n$ ) covariant and logarithmic translation covariant valuation.

Proof. Let $f, g \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$ and $E=\left\{x \in \mathbb{R}^{n}: f(x) \leq g(x)\right\}$. Then

$$
\begin{aligned}
z(f \vee g)(x) & =\int_{\mathbb{R}^{n}} h \circ(f \vee g)(y) e^{-x \cdot y} d y \\
& =\int_{E}(h \circ g)(y) e^{-x \cdot y} d y+\int_{\mathbb{R}^{n} \backslash E}(h \circ f)(y) e^{-x \cdot y} d y
\end{aligned}
$$

for every $x \in \mathbb{R}^{n}$. Similarly, we have

$$
\begin{aligned}
z(f \wedge g)(x) & =\int_{\mathbb{R}^{n}} h \circ(f \wedge g)(y) e^{-x \cdot y} d y \\
& =\int_{E}(h \circ f)(y) e^{-x \cdot y} d y+\int_{\mathbb{R}^{n} \backslash E}(h \circ g)(y) e^{-x \cdot y} d y
\end{aligned}
$$

for every $x \in \mathbb{R}^{n}$. Thus,

$$
\begin{aligned}
& z(f \vee g)(x)+z(f \wedge g)(x) \\
= & \int_{\mathbb{R}^{n}}(h \circ f)(y) e^{-x \cdot y} d y+\int_{\mathbb{R}^{n}}(h \circ g)(y) e^{-x \cdot y} d y \\
= & z(f)(x)+z(g)(x)
\end{aligned}
$$

for every $x \in \mathbb{R}^{n}$.
Next, we are going to show that $z$ is continuous. Let $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$ and let $\left\{f_{i}\right\}$ be a sequence in $L_{c}^{1}\left(\mathbb{R}^{n}\right)$ that converges to $f$ in $L^{1}\left(\mathbb{R}^{n}\right)$. We will show the continuity of $z$ by showing that for every subsequence $\left\{z\left(f_{i_{j}}\right)(x)\right\}$ of $\left\{z\left(f_{i}\right)(x)\right\}$, there exists a subsequence $\left\{z\left(f_{i_{j_{k}}}\right)(x)\right\}$ that converges to $z(f)(x)$ for every $x \in \mathbb{R}^{n}$.

Let $\left\{f_{i_{j}}\right\}$ be a subsequence of $\left\{f_{i}\right\}$ and $y \in \mathbb{R}^{n}$. Then, for every $x \in \mathbb{R}^{n}$, the sequence of functions $y \mapsto f_{i_{j}}(y) e^{-x \cdot y}$ converges to the function $y \mapsto f(y) e^{-x \cdot y}$ as $j \rightarrow \infty$ with respect to the $L^{1}$ norm. It follows that there exists a subsequence $\left\{f_{i_{j_{k}}}\right\}$ of $\left\{f_{i_{j}}\right\}$ and a nonnegative function $F_{x} \in L^{1}\left(\mathbb{R}^{n}\right)$ such that
(i) $f_{i_{j_{k}}}(y) e^{-x \cdot y} \rightarrow f(y) e^{-x \cdot y}$ almost every $y$ with respect to Lebesgue measure;
(ii) $\left|f_{i_{j_{k}}}(y)\right| e^{-x \cdot y} \leq F_{x}(y)$ almost every $y$ with respect to Lebesgue measure (see [23, Section 2.7]). Since $h$ is continuous, we obtain

$$
h \circ f_{i_{j_{k}}} \rightarrow h \circ f \quad \text { a.e. }
$$

Also since $h$ satisfies (1.3), we have

$$
\left|h \circ f_{i_{j_{k}}}(y)\right| \leq \gamma\left|f_{i_{j_{k}}}(y)\right| \leq \gamma F_{x}(y) e^{x \cdot y} .
$$

Note that $\int_{\mathbb{R}^{n}} F_{x}(y) e^{x \cdot y} \cdot e^{-x \cdot y} d y<\infty$. We conclude from the dominated convergence theorem that

$$
z(f)(x)=\int_{\mathbb{R}^{n}}(h \circ f)(y) e^{-x \cdot y} d y=\lim _{k \rightarrow \infty} \int_{\mathbb{R}^{n}}\left(h \circ f_{i_{j_{k}}}\right)(y) e^{-x \cdot y} d y=\lim _{k \rightarrow \infty} z\left(f_{i_{j_{k}}}\right)(x) .
$$

Moreover, for $\phi \in \mathrm{GL}(n)$,

$$
\begin{aligned}
z\left(f \circ \phi^{-1}\right)(x) & =\int_{\mathbb{R}^{n}}\left(h \circ f \circ \phi^{-1}\right)(y) e^{-x \cdot y} d y \\
& =|\operatorname{det} \phi| \int_{\mathbb{R}^{n}}(h \circ f)(w) e^{-x \cdot(\phi w)} d w \\
& =|\operatorname{det} \phi| \int_{\mathbb{R}^{n}}(h \circ f)(w) e^{-\left(\phi^{t} x\right) \cdot w} d w \\
& =|\operatorname{det} \phi| z(f)\left(\phi^{t} x\right)
\end{aligned}
$$

for every $x \in \mathbb{R}^{n}$ and $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$. Finally, let $t \in \mathbb{R}^{n}$. Then

$$
\begin{aligned}
z(f(\cdot-t))(x) & \left.=\int_{\mathbb{R}^{n}}(h \circ f)(y-t)\right) e^{-x \cdot y} d y \\
& =\int_{\mathbb{R}^{n}}(h \circ f)(w) e^{-x \cdot(w+t)} d w \\
& =e^{-x \cdot t} \int_{\mathbb{R}^{n}}(h \circ f)(w) e^{-x \cdot w} d w \\
& =e^{-x \cdot t} z(f)(x)
\end{aligned}
$$

for every $x \in \mathbb{R}^{n}$ and $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$.
Next, we turn to the Laplace transform on convex bodies.
Lemma 3.2. If $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation, then for any $\alpha \in \mathbb{R}, Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ defined by

$$
Z K=z\left(\alpha \mathbb{1}_{K}\right)
$$

is a continuous, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation on $\mathcal{K}_{n}^{n}$.
Proof. For $K, L, K \cup L, K \cap L \in \mathcal{K}_{n}^{n}$, we have

$$
\begin{aligned}
Z(K \cup L)+Z(K \cap L) & =z\left(\alpha \mathbb{1}_{K \cup L}\right)+z\left(\alpha \mathbb{1}_{K \cap L}\right) \\
& =z\left(\left(\alpha \mathbb{1}_{K}\right) \vee\left(\alpha \mathbb{1}_{L}\right)\right)+z\left(\left(\alpha \mathbb{1}_{K}\right) \wedge\left(\alpha \mathbb{1}_{L}\right)\right) \\
& =z\left(\alpha \mathbb{1}_{K}\right)+z\left(\alpha \mathbb{1}_{L}\right) \\
& =Z K+Z L .
\end{aligned}
$$

Also, for a sequence $\left\{K_{i}\right\}$ in $\mathcal{K}_{n}^{n}$ that converges to $K \in \mathcal{K}_{n}^{n}$ as $i \rightarrow \infty$, we have $\left\|\alpha \mathbb{1}_{K_{i}}-\alpha \mathbb{1}_{K}\right\| \rightarrow 0$ as $i \rightarrow \infty$. Indeed, for any $0<\varepsilon \leq 1$, we have

$$
K_{i} \subset K+\varepsilon B, \quad K \subset K_{i}+\varepsilon B
$$

for sufficiently large $i$. Hence $\left(K_{i} \backslash K\right) \cup\left(K \backslash K_{i}\right) \subset\{x: \exists y \in \operatorname{bd} K$, s.t. $d(x, y) \leq \varepsilon\}$, where bd $K$ is the boundary of $K$. Hence,

$$
\begin{aligned}
\int_{\mathbb{R}^{n}}\left|\alpha \mathbb{1}_{K_{i}}(y)-\alpha \mathbb{1}_{K}(y)\right| d y & \leq|\alpha| V_{n}(\{x: \exists y \in \text { bd } K, \text { s.t. } d(x, y) \leq \varepsilon\}) \\
& \leq|\alpha| \cdot 2 \varepsilon S(K+B)
\end{aligned}
$$

for sufficiently large $i$. Here, $S$ denotes the surface area. By the continuity of $z$ on $L_{c}^{1}\left(\mathbb{R}^{n}\right)$, we obtain

$$
Z\left(K_{i}\right)=z\left(\alpha \mathbb{1}_{K_{i}}\right) \rightarrow z\left(\alpha \mathbb{1}_{K}\right)=Z K
$$

as $i \rightarrow \infty$. Moreover, for each $\phi \in \mathrm{GL}(n)$ and $K \in \mathcal{K}_{n}^{n}$, we have

$$
\begin{aligned}
Z(\phi K) & =z\left(\alpha \mathbb{1}_{\phi K}\right)=z\left(\alpha \mathbb{1}_{K} \circ \phi^{-1}\right) \\
& =|\operatorname{det} \phi| z\left(\alpha \mathbb{1}_{K}\right) \circ \phi^{t}=|\operatorname{det} \phi| Z K \circ \phi^{t} .
\end{aligned}
$$

Finally, for each $t, x \in \mathbb{R}^{n}$, we have

$$
\begin{aligned}
Z(K+t)(x) & =z\left(\alpha \mathbb{1}_{K+t}\right)(x)=z\left(\alpha \mathbb{1}_{K}(\cdot-t)\right)(x) \\
& =e^{-t \cdot x} z\left(\alpha \mathbb{1}_{K}\right)(x)=e^{-t \cdot x} Z K(x) .
\end{aligned}
$$

The following theorem directly follows from the definition of the Laplace transform, Theorem 3.1 and Lemma 3.2.

Theorem 3.3. The Laplace transform on $\mathcal{K}_{n}^{n}$ is a continuous, GL( $n$ ) covariant and logarithmic translation covariant valuation.

## 4 Characterizations of Laplace transforms

In this section, we first characterize the Laplace transform on $\mathcal{K}_{n}^{n}$ as a continuous, GL $(n)$ covariant and logarithmic translation covariant valuation. Afterwards, via an approach developed from Tsang's in [43], we further characterize the Laplace transform on $L_{c}^{1}\left(\mathbb{R}^{n}\right)$.

### 4.1 The Laplace transform on convex bodies

We first need to extend the valuation to $\mathcal{K}^{n}$.
Lemma 4.1. If $Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation, then $\bar{Z}: \mathcal{K}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ defined by

$$
\bar{Z} K(x)= \begin{cases}Z K(x), & \operatorname{dim} K=n \\ 0, & \operatorname{dim} K<n\end{cases}
$$

is a simple, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation on $\mathcal{K}^{n}$.
Proof. The GL $(n)$ covariance and the logarithmic translation covariance are trivial. It remains to show that

$$
\begin{equation*}
Z K(x)=Z\left(K \cap H^{+}\right)(x)+Z\left(K \cap H^{-}\right)(x), \quad x \in \mathbb{R}^{n} \tag{4.1}
\end{equation*}
$$

for every hyperplane $H$ (when $n=1, H$ is a single point) such that $K, K \cap H^{+}, K \cap H^{-} \in \mathcal{K}_{n}^{n}$. Since $Z$ is logarithmic translation covariant, we can assume w.l.o.g. that $o \in(\operatorname{int} K \cap H)$. We can further assume that $e_{n} \perp H$ and $e_{n} \in H^{+}$due to the GL $(n)$ covariace of $Z$. For a fixed $K$, note that $\pm s e_{n} \in K$ for sufficiently small $s>0$. Hence the valuation property of $Z$ shows that

$$
\begin{equation*}
Z K(x)+Z\left[K \cap H, \pm s e_{n}\right](x)=Z\left[K \cap H^{+},-s e_{n}\right](x)+Z\left[K \cap H^{-}, s e_{n}\right](x) \tag{4.2}
\end{equation*}
$$

for every $x \in \mathbb{R}^{n}$ and sufficiently small $s>0$. The $\mathrm{GL}(n)$ covariance of $Z$ gives that

$$
Z\left[K \cap H, \pm s e_{n}\right](x)=s Z\left[K \cap H, \pm e_{n}\right]\left(x_{1} e_{1}+\cdots+x_{n-1} e_{n-1}+s x_{n} e_{n}\right)
$$

where $x=x_{1} e_{1}+\cdots+x_{n} e_{n} \in \mathbb{R}^{n}$. Since

$$
\begin{aligned}
& \lim _{s \rightarrow 0^{+}} Z\left[K \cap H, \pm e_{n}\right]\left(x_{1} e_{1}+\cdots+x_{n-1} e_{n-1}+s x_{n} e_{n}\right) \\
& =Z\left[K \cap H, \pm e_{n}\right]\left(x_{1} e_{1}+\cdots+x_{n-1} e_{n-1}\right),
\end{aligned}
$$

we have

$$
\begin{equation*}
\lim _{s \rightarrow 0^{+}} Z\left(\left[K \cap H, \pm s e_{n}\right]\right)(x) \rightarrow 0 \tag{4.3}
\end{equation*}
$$

Now combing (4.2) and (4.3) with the continuity of $Z$, we get that (4.1) holds true.
Next we consider $Z C^{n}$.

Lemma 4.2. If $Z: \mathcal{K}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is a simple, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation, then there exists a constant $c \in \mathbb{R}$ such that

$$
\begin{equation*}
Z C^{n}\left(r e_{1}\right)=c \mathcal{L} C^{n}\left(r e_{1}\right)=c \int_{C^{n}} e^{-r e_{1} \cdot y} d y \tag{4.4}
\end{equation*}
$$

for every $r \in \mathbb{R}$.
Proof. First note that

$$
\begin{equation*}
\int_{C^{n}} e^{-r e_{1} \cdot y} d y=\frac{1}{r}\left(1-e^{-r}\right) . \tag{4.5}
\end{equation*}
$$

For $s>0$, let $\psi_{s} \in \operatorname{GL}(n)$ such that $\psi_{s} e_{1}=s e_{1}$ and $\psi_{s} e_{k}=e_{k}$ for $2 \leq k \leq n$. For integers $p, q>0$, since $Z$ is simple, we have

$$
Z\left(\psi_{q / p} C^{n}\right)\left(e_{1}\right)=\sum_{j=0}^{q-1} Z\left(\psi_{1 / p} C^{n}+\frac{j e_{1}}{p}\right)\left(e_{1}\right)
$$

Also since $Z$ is $\mathrm{GL}(n)$ and logarithmic translation covariant, we have

$$
\begin{aligned}
\frac{q}{p} Z C^{n}\left(\frac{q}{p} e_{1}\right) & =\frac{1}{p} \sum_{j=0}^{q-1} e^{-j / p} Z C^{n}\left(\frac{e_{1}}{p}\right) \\
& =\frac{1}{p} Z C^{n}\left(\frac{e_{1}}{p}\right) \frac{1-e^{-q / p}}{1-e^{-1 / p}}
\end{aligned}
$$

In particular, if $q=p$, we have

$$
Z C^{n}\left(\frac{e_{1}}{p}\right)=\frac{p\left(1-e^{-1 / p}\right)}{1-e^{-1}} Z C^{n}\left(e_{1}\right) .
$$

Combining the two formulas above with (4.5), and letting $c=\frac{Z C^{n}\left(e_{1}\right)}{1-e^{-1}}$, (4.4) holds for $r=q / p$. Now since $Z C^{n}$ is a continuous function on $\mathbb{R}^{n}$, (4.4) holds for $r \geq 0$.

For $r<0$. Repeating the same process for $-e_{1}$, we obtain

$$
\begin{aligned}
\frac{q}{p} Z C^{n}\left(-\frac{q}{p} e_{1}\right) & =\frac{1}{p} \sum_{j=0}^{q-1} e^{j / p} Z C^{n}\left(-\frac{e_{1}}{p}\right) \\
& =\frac{1}{p} Z C^{n}\left(-\frac{e_{1}}{p}\right) \frac{1-e^{q / p}}{1-e^{1 / p}}
\end{aligned}
$$

and

$$
Z C^{n}\left(-\frac{e_{1}}{p}\right)=\frac{p\left(1-e^{1 / p}\right)}{1-e} Z C^{n}\left(-e_{1}\right)
$$

Combining the two formulas above and letting $c^{\prime}=-\frac{Z C^{n}\left(-e_{1}\right)}{1-e}$, we have

$$
Z C^{n}\left(r e_{1}\right)=c^{\prime} \int_{C^{n}} e^{-r e_{1} \cdot y} d y
$$

for $r=-q / p$. The continuity of the function $Z C^{n}$ gives that $c=c^{\prime}$ and thus (4.4) holds for $r \leq 0$.

Now we consider valuations on polytopes. Let $\mathcal{P}^{n}$ denote the set of polytopes in $\mathbb{R}^{n}$ and let $Z: \mathcal{P}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ be a valuation. The inclusion-exclusion principle states that $Z$ extends uniquely to $U(\mathcal{P})$, the set of finite unions of polytopes, with

$$
Z\left(P_{1} \cup \cdots \cup P_{m}\right)=\sum_{1 \leq j \leq m}(-1)^{j-1} \sum_{1 \leq i_{1}<\cdots<i_{j} \leq m} Z\left(P_{i_{1}} \cap \cdots \cap P_{i_{j}}\right)
$$

for every $P_{1}, \ldots, P_{m} \in \mathcal{P}^{n}$ (see [31] or [39, Theorem 6.2.1 and Theorem 6.2.3]).
Lemma 4.3. If $Z: \mathcal{P}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is a simple, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation such that

$$
\begin{equation*}
Z C^{n}\left(r e_{1}\right)=0 \tag{4.6}
\end{equation*}
$$

for every $r \in \mathbb{R}$, then

$$
Z T^{n}\left(r e_{1}\right)=0
$$

for every $r \in \mathbb{R}$.
Proof. The case $n=1$ is trivial. We only consider $n \geq 2$.
First we prove that $Z T^{n}(o)=0$. Since $C^{n}=\bigcup_{1 \leq i_{1}<\cdots<i_{n} \leq n}\left\{x \in \mathbb{R}^{n}: 0 \leq x_{i_{1}} \leq \cdots \leq\right.$ $\left.x_{i_{n}} \leq 1\right\}$, and all the sets $\left\{x \in \mathbb{R}^{n}: 0 \leq x_{i_{1}} \leq \cdots \leq x_{i_{n}} \leq 1\right\}$ are GL( $n$ ) transform (with positive determinant) images of $T^{n}$, the valuation property, simplicity, and GL( $n$ ) covariance of $Z$ combined with (4.6) give that

$$
Z T^{n}(o)=0 .
$$

Next we deal with the case $r \neq 0$. Let $g(m, s)=Z\left(m T^{n}\right)\left(s e_{1}\right)$ for $s \in \mathbb{R}$ and integer $m \geq 0$. For integer $k \geq 1$, denote $M_{k}^{n}=k T^{n} \cap C^{n}$. Note that when $k \geq n$, we have

$$
\begin{equation*}
M_{k}^{n}=C^{n} . \tag{4.7}
\end{equation*}
$$

For $1 \leq k \leq n-1$,

$$
\begin{equation*}
k T^{n} \cup C^{n}=\left(\bigcup_{j=1}^{n}\left(k T^{n} \cap\left\{x \in \mathbb{R}^{n}: x_{j} \geq 1\right\}\right)\right) \cup C^{n} \tag{4.8}
\end{equation*}
$$

Denote $T_{j}=k T^{n} \cap\left\{x \in \mathbb{R}^{n}: x_{j} \geq 1\right\}$. We have

$$
T_{j}=(k-1) T^{n}+e_{j},
$$

and

$$
T_{j_{1}} \cap \cdots \cap T_{j_{i}}=(k-i) T^{n}+e_{j_{1}}+\cdots+e_{j_{i}}
$$

for $i \leq k$ and $1 \leq j_{1}<\cdots<j_{i} \leq n$. Hence, the valuation property (after extension), inclusion-exclusion principle, simplicity and logarithmic translation covariance of $Z$, combined with (4.6) and (4.8), give that

$$
\begin{align*}
Z\left(M_{k}^{n}\right)\left(s e_{1}\right) & =Z\left(k T^{n}\right)\left(s e_{1}\right)-Z\left(k T^{n} \cup C^{n}\right)\left(s e_{1}\right) \\
& =Z\left(k T^{n}\right)\left(s e_{1}\right)-\left(\sum_{i=1}^{k-1}(-1)^{i-1} \sum_{1 \leq j_{1}<\cdots<j_{i} \leq n} Z\left(T_{j_{1}} \cap \cdots \cap T_{j_{i}}\right)\left(s e_{1}\right)\right) \\
& =Z\left(k T^{n}\right)\left(s e_{1}\right)-\left(\sum_{i=1}^{k-1}(-1)^{i-1}\left(\binom{n-1}{i-1} e^{-s}+\binom{n-1}{i}\right) Z\left((k-i) T^{n}\right)\left(s e_{1}\right)\right) \\
& =\sum_{i=0}^{k-1}(-1)^{i} a_{i}(s) g(k-i, s), \tag{4.9}
\end{align*}
$$

where $1 \leq k \leq n-1, a_{i}(s)=\binom{n-1}{i-1} e^{-s}+\binom{n-1}{i}$ for $1 \leq i \leq n-1$, and $a_{0}(s)=1$.
For non negative integers $k_{1}, \ldots, k_{n}$ satisfying $k=k_{1}+\cdots+k_{n} \leq m-1$, we have

$$
m T^{n} \cap\left(C^{n}+k_{1} e_{1}+\cdots+k_{n} e_{n}\right)=M_{m-k}^{n}+k_{1} e_{1}+\cdots+k_{n} e_{n} .
$$

For $m \geq n$, applying the valuation property, simplicity, logarithmic translation covariance of
$Z$, (4.6), (4.7) and (4.9), we have

$$
\begin{align*}
g(m, s) & =Z\left(m T^{n}\right)\left(s e_{1}\right) \\
& =\sum_{k=0}^{m-1} \sum_{\substack{k_{1}+\ldots+k_{n}=k, k_{1}, \ldots, k_{n} \geq 0}} Z\left(m T^{n} \cap\left(C^{n}+k_{1} e_{1}+\cdots+k_{n} e_{n}\right)\right)\left(s e_{1}\right) \\
& =\sum_{k=0}^{m-1} \sum_{\substack{k_{1}+\ldots+k_{n}=k, k_{1}, \ldots, k_{n} \geq 0}} Z\left(M_{m-k}^{n}+k_{1} e_{1}+\cdots+k_{n} e_{n}\right)\left(s e_{1}\right) \\
& =\sum_{k=0}^{m-1} \sum_{k_{1}=0}^{k} e^{-k_{1} s} \sum_{\substack{k_{2}+\ldots+k_{n}=k-k_{1}, k_{2}, \ldots, k_{n} \geq 0 \\
k}} Z\left(M_{m-k}^{n}\right)\left(s e_{1}\right) \\
& =\sum_{k=0}^{m-1} Z\left(M_{m-k}^{n}\right)\left(s e_{1}\right) \sum_{k_{1}=0}^{k} e^{-k_{1} s}\binom{k-k_{1}+n-2}{n-2} \\
& =\sum_{k=m}^{m-1}\left(\sum_{i=0}^{m-k-1}(-1)^{i} a_{i}(s) g(m-k-i, s)\right)\left(\sum_{k_{1}=0}^{k} e^{-k_{1} s}\binom{\left.k-k_{1}+n-2\right)}{n-2}\right) \\
& =\sum_{j=1}^{n-1} b_{j}(m, s) g(j, s), \tag{4.10}
\end{align*}
$$

where $b_{j}(m, s)=\sum_{k=m-n+1}^{m-j}(-1)^{m-k-j} a_{m-k-j}(s) \sum_{k_{1}=0}^{k} e^{-k_{1} s}\binom{k-k_{1}+n-2}{n-2}$ for $1 \leq j \leq n-1$.
Since $Z$ is GL $(n)$ covariant, we have

$$
g(m, s)=m^{n} g(1, m s) .
$$

Hence the equation (4.10) gives that

$$
\begin{equation*}
g(1, m s)=\sum_{j=1}^{n-1}(j / m)^{n} b_{j}(m, s) g(1, j s) . \tag{4.11}
\end{equation*}
$$

For any fixed $r \neq 0$, taking $s=r / m$ in (4.11), we get

$$
\begin{equation*}
g(1, r)=\sum_{j=1}^{n-1}(j / m)^{n} b_{j}(m, r / m) g(1, j r / m) \tag{4.12}
\end{equation*}
$$

Since $g(1, \cdot)$ is a continuous function and $g(1,0)=Z T^{n}(o)=0$, if we can show that $(j / m)^{n} b_{j}(m, r / m)$ is finite when $m \rightarrow \infty$, then $g(1, r)=0$ which gives the desired result for $r \neq 0$.

Indeed, for sufficiently large $m,(m+n) / m \leq 2$ and $a_{i}(r / m), 1 \leq i \leq n-1$ are smaller than a constant $N>0$. Hence, for $1 \leq j \leq n-1$,

$$
\begin{aligned}
\left|(j / m)^{n} b_{j}(m, r / m)\right| & \leq(n / m)^{n} \sum_{k=m-n+1}^{m-j} a_{m-k-j}(r / m) \sum_{k_{1}=0}^{k} e^{-k_{1} r / m}\binom{k-k_{1}+n-2}{n-2} \\
& \leq(n / m)^{n} \sum_{k=m-n+1}^{m-j} a_{m-k-j}(r / m) \sum_{k_{1}=0}^{k} e^{-k_{1} r / m}(m+n)^{n-2} \\
& =(m+n)^{n-2}(n / m)^{n} \sum_{k=m-n+1}^{m-j} a_{m-k-j}(r / m) \frac{\mid 1-e^{-(k+1) r / m \mid}}{\mid 1-e^{-r / m \mid}} \\
& \leq 2^{n-2} n^{n} N(1 / m)^{2} \sum_{k=m-n+1}^{m-j} \frac{\left|1-e^{-(k+1) r / m}\right|}{\left|1-e^{-r / m}\right|} \\
& \leq 2^{n-2} n^{n} N(1 / m)^{2} \frac{(n-j) \max \left\{1, e^{-r}\right\}}{\left|1-e^{-r / m}\right|} .
\end{aligned}
$$

Note that $(1 / m)^{2} \frac{1}{\mid 1-e^{-r / m \mid}} \rightarrow 0$ when $m \rightarrow \infty$. Hence $(j / m)^{n} b_{j}(m, r / m) \rightarrow 0$ when $m \rightarrow$ $\infty$.

For $0<\lambda<1$, let $H_{\lambda}$ be the hyperplane through the origin with normal vector ( $1-$ $\lambda) e_{1}-\lambda e_{2}$. Since $Z: \mathcal{P}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is a simple valuation,

$$
\begin{equation*}
Z T^{n}(x)=Z\left(T^{n} \cap H_{\lambda}^{-}\right)(x)+Z\left(T^{n} \cap H_{\lambda}^{+}\right)(x), \quad x \in \mathbb{R}^{n} . \tag{4.13}
\end{equation*}
$$

We define $\phi_{1}, \phi_{2} \in \mathrm{GL}(n)$ by

$$
\phi_{1} e_{1}=\lambda e_{1}+(1-\lambda) e_{2}, \quad \phi_{1} e_{2}=e_{2}, \quad \phi_{1} e_{i}=e_{i}, \text { for } 3 \leq i \leq n,
$$

and

$$
\phi_{2} e_{1}=e_{1}, \phi_{2} e_{2}=\lambda e_{1}+(1-\lambda) e_{2}, \phi_{2} e_{i}=e_{i}, \text { for } 3 \leq i \leq n .
$$

Note that $T^{n} \cap H_{\lambda}^{-}=\phi_{1} T^{n}, T^{n} \cap H_{\lambda}^{+}=\phi_{2} T^{n}$. The GL $(n)$ covariance of $Z$ and valuation relation (4.13) show that

$$
Z T^{n}(x)=\lambda Z T^{n}\left(\phi_{1}^{t} x\right)+(1-\lambda) Z T^{n}\left(\phi_{2}^{t} x\right)
$$

Let $f(\cdot)=Z T^{n}(\cdot)$. We have

$$
\begin{equation*}
f(x)=\lambda f\left(\phi_{1}^{t} x\right)+(1-\lambda) f\left(\phi_{2}^{t} x\right) \tag{4.14}
\end{equation*}
$$

for every $0<\lambda<1$ and $x=\left(x_{1}, \ldots, x_{n}\right)^{t} \in \mathbb{R}^{n}$, where $\phi_{1}^{t} x=\left(\lambda x_{1}+(1-\lambda) x_{2}, x_{2}, x_{3}, \ldots, x_{n}\right)^{t}$ and $\phi_{2}^{t} x=\left(x_{1}, \lambda x_{1}+(1-\lambda) x_{2}, x_{3}, \ldots, x_{n}\right)^{t}$.

Lemma 4.4. Let $n \geq 2$ and let the function $f \in C\left(\mathbb{R}^{n}\right)$ satisfy the following properties.
(i) $f$ satisfies the functional equation (4.14);
(ii) For every even permutation $\pi$ and $x \in \mathbb{R}^{n}$,

$$
f(x)=f(\pi x)
$$

If $f\left(r e_{1}\right)=0$ for every $r \in \mathbb{R}$, then

$$
f(x)=0
$$

for every $x \in \mathbb{R}^{n}$.
Proof. We prove the statement by induction on the number $m$ of coordinates of $x$ not equal to zero. By property (ii), we can assume that the first $m$ coordinates of $x$ are not equal to zero.

It is trivial that the statement is true for $m=1$. Assume that the statement holds true for $m-1$. We want to show that

$$
\begin{equation*}
f\left(x_{1} e_{1}+\cdots+x_{m} e_{m}\right)=0 \tag{4.15}
\end{equation*}
$$

for all the $x_{1}, \ldots, x_{m}$ not zero. For $x_{1}>x_{2}>0$ or $0>x_{2}>x_{1}$, taking $x=x_{1} e_{1}+x_{3} e_{3}+$ $\cdots+x_{m} e_{m}, \lambda=\frac{x_{2}}{x_{1}}$ in (4.14), we get

$$
\begin{align*}
& f\left(x_{1} e_{1}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right) \\
& =\frac{x_{2}}{x_{1}} f\left(x_{2} e_{1}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right)+\left(1-\frac{x_{2}}{x_{1}}\right) f\left(x_{1} e_{1}+x_{2} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right) \tag{4.16}
\end{align*}
$$

For $x_{2}>x_{1}>0$ or $0>x_{1}>x_{2}$, taking $x=x_{2} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}, 1-\lambda=\frac{x_{1}}{x_{2}}$ in (4.14), we get

$$
\begin{align*}
& f\left(x_{2} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right) \\
& =\left(1-\frac{x_{1}}{x_{2}}\right) f\left(x_{1} e_{1}+x_{2} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right)+\frac{x_{1}}{x_{2}} f\left(x_{1} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right) . \tag{4.17}
\end{align*}
$$

For $x_{1}>0>x_{2}$ or $x_{2}>0>x_{1}$, taking $0<\lambda=\frac{x_{2}}{x_{2}-x_{1}}<1$ and $x=x_{1} e_{1}+x_{2} e_{2}+x_{3} e_{3}+\cdots+$ $x_{m} e_{m}$ in (4.14), we get

$$
\begin{align*}
& f\left(x_{1} e_{1}+x_{2} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right) \\
= & \frac{x_{2}}{x_{2}-x_{1}} f\left(x_{2} e_{2}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right)+\frac{-x_{1}}{x_{2}-x_{1}} f\left(x_{1} e_{1}+x_{3} e_{3}+\cdots+x_{m} e_{m}\right) . \tag{4.18}
\end{align*}
$$

Now, combined with the induction assumption and the continuity of $f,(4.16),(4.17)$ and (4.18) show that (4.15) holds true.

Proof of Theorem 1.2. By Theorem 3.3, $c \mathcal{L}$ is a continuous, GL $(n)$ covariant and logarithmic translation covariant valuation on $\mathcal{K}_{n}^{n}$.

Now we turn to the reverse statement. Since $Z: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, $\operatorname{GL}(n)$ covariant and logarithmic translation covariant valuation, Lemma 4.1 allows us to extend this valuation to a simple, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation on $\mathcal{K}^{n}$. Hence Lemma 4.2 gives that there exists a constant $c \in \mathbb{R}$ such that

$$
Z C^{n}\left(r e_{1}\right)=c \mathcal{L} C^{n}\left(r e_{1}\right)
$$

for every $r \in \mathbb{R}$. Now define $Z^{\prime}: \mathcal{P}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ by

$$
Z^{\prime} P(x)=Z P(x)-c \mathcal{L} P(x), \quad x \in \mathbb{R}^{n}
$$

It is easy to see that $Z^{\prime}$ is also a simple, $\mathrm{GL}(n)$ covariant and logarithmic translation covariant valuation on $\mathcal{K}^{n}$. Also $Z^{\prime} C^{n}\left(r e_{1}\right)=0$ for every $r \in \mathbb{R}$. Applying Lemma 4.3 (for $Z^{\prime}$ ) and Lemma 4.4 (for $f=Z^{\prime} T^{n}$ ) we get

$$
Z^{\prime} T^{n}=0
$$

Now using the inclusion-exclusion principle and the GL $(n)$ covariance and the simplicity of $Z^{\prime}$ again, we have

$$
Z^{\prime} P=0
$$

for every $P \in \mathcal{P}^{n}$ since every $P \in \mathcal{P}^{n}$ can be dissected into finite pieces of GL( $n$ ) (with positive determinant) transforms and translations of $T^{n}$. Hence

$$
Z P=c \mathcal{L} P
$$

for every $P \in \mathcal{P}^{n}$. Since both $Z$ and $\mathcal{L}$ are continuous on $\mathcal{K}_{n}^{n}$,

$$
Z K=c \mathcal{L} K
$$

for every $K \in \mathcal{K}_{n}^{n}$.

### 4.2 Laplace transforms on functions

We first consider indicator functions of Borel sets.
Lemma 4.5. If a map $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ is a continuous, $\operatorname{GL}(n)$ covariant and logarithmic translation covariant valuation, then there exists a continuous function $h$ on $\mathbb{R}$ satisfying (1.2) and (1.3) such that

$$
z\left(\alpha \mathbb{1}_{E}\right)(x)=h(\alpha) \int_{\mathbb{R}^{n}} \mathbb{1}_{E}(y) e^{-x \cdot y} d y
$$

for every $\alpha \in \mathbb{R}, x \in \mathbb{R}^{n}$ and bounded Borel set $E \subset \mathbb{R}^{n}$.
Proof. For any $\alpha \in \mathbb{R}$, define $Z_{\alpha}: \mathcal{K}_{n}^{n} \rightarrow C\left(\mathbb{R}^{n}\right)$ by

$$
Z_{\alpha} K=z\left(\alpha \mathbb{1}_{K}\right)
$$

for every $K \in \mathcal{K}_{n}^{n}$. Lemma 3.2 shows that $Z_{\alpha}$ is a continuous, $\operatorname{GL}(n)$ and logarithmic translation covariant valuation on $\mathcal{K}_{n}^{n}$.

Therefore, by Theorem 1.2, there exists a function $h \in \mathbb{R}$ such that

$$
\begin{aligned}
z\left(\alpha \mathbb{1}_{K}\right)(x)=Z_{\alpha} K(x) & =h(\alpha) \mathcal{L} K(x) \\
& =h(\alpha) \int_{K} e^{-x \cdot y} d y=h(\alpha) \int_{\mathbb{R}^{n}} \mathbb{1}_{K}(y) e^{-x \cdot y} d y
\end{aligned}
$$

for every $K \in \mathcal{K}_{n}^{n}$ and $x \in \mathbb{R}^{n}$. The function $h$ is continuous since $z$ is continuous and $\left\|\alpha_{i} \mathbb{1}_{K}-\alpha \mathbb{1}_{K}\right\| \rightarrow 0$ whenever $\alpha_{i} \rightarrow \alpha . z(0)=0$ (see (2.2)) gives that $h(0)=0$. In particular, this representation holds on $\operatorname{Par}(n)$, the set of finite union of cubes, by the inclusion-exclusion principle.

Now we consider Borel sets in $\mathbb{R}^{n}$. For each bounded Borel set $E \subset \mathbb{R}^{n}$, there exists a sequence $\left\{K_{i}\right\}$ in $\operatorname{Par}(n)$ such that $\alpha \mathbb{1}_{K_{i}} \rightarrow \alpha \mathbb{1}_{E}$ in $L_{c}^{1}\left(\mathbb{R}^{n}\right)$ for every $\alpha \in \mathbb{R}$ as $i \rightarrow \infty$. Moreover, for every $x \in \mathbb{R}^{n}$,

$$
\begin{aligned}
0 \leq \lim _{i \rightarrow \infty}\left|\int_{\mathbb{R}^{n}}\left(\mathbb{1}_{K_{i}}(y)-\mathbb{1}_{E}(y)\right) e^{-x \cdot y} d y\right| & \leq \lim _{i \rightarrow \infty} \int_{\mathbb{R}^{n}}\left|\mathbb{1}_{K_{i}}(y)-\mathbb{1}_{E}(y)\right| e^{-x \cdot y} d y \\
& \leq \max _{y \in E} e^{-x \cdot y} \lim _{i \rightarrow \infty} \int_{\mathbb{R}^{n}}\left|\mathbb{1}_{K_{i}}(y)-\mathbb{1}_{E}(y)\right| d y \\
& =0
\end{aligned}
$$

Thus, the continuity of $z$ gives that

$$
\begin{aligned}
z\left(\alpha \mathbb{1}_{E}\right)(x)=\lim _{i \rightarrow \infty} z\left(\alpha \mathbb{1}_{K_{i}}\right)(x) & =h(\alpha) \lim _{i \rightarrow \infty} \int_{\mathbb{R}^{n}} \mathbb{1}_{K_{i}}(y) e^{-x \cdot y} d y \\
& =h(\alpha) \int_{\mathbb{R}^{n}} \mathbb{1}_{E}(y) e^{-x \cdot y} d y
\end{aligned}
$$

The last step is to show that $h$ satisfies (1.3). If $h$ does not satisfy (1.3), then there exists a sequence $\left\{\alpha_{j}\right\}$ in $\mathbb{R} \backslash\{0\}$ (since $h$ satisfies (1.2)) such that

$$
\begin{equation*}
\left|h\left(\alpha_{j}\right)\right|>2^{i}\left|\alpha_{j}\right| \tag{4.19}
\end{equation*}
$$

Set $E_{j}=\left[0,2^{-j} /\left|\alpha_{j}\right|\right] \times[0,1]^{n-1}$. We have

$$
\int_{E_{j}} d y=\frac{2^{-j}}{\left|\alpha_{j}\right|}
$$

Let $g_{j}=\alpha_{j} \mathbb{1}_{E_{j}}$ and $f \equiv 0$. Clearly $g_{j}, f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$. Since

$$
\int_{\mathbb{R}^{n}}\left|g_{j}(y)\right| d y=\left|\alpha_{j}\right| \int_{E_{j}} d y=2^{-j} \rightarrow 0
$$

when $j \rightarrow \infty$. Hence $\left\|g_{j}-f\right\| \rightarrow 0$. The continuity of $z$ now implies that

$$
z(f)(o)=\lim _{j \rightarrow \infty} z\left(g_{j}\right)(o) d y
$$

On the other hand, $z(f)(o)=0$ (see (2.2)) and the above statement gives that

$$
z\left(g_{j}\right)(o)=h\left(\alpha_{j}\right) \int_{\mathbb{R}^{n}} \mathbb{1}_{E_{j}}(y) d y
$$

However, since $h$ satisfies (4.19), we obtain

$$
\begin{aligned}
0=|z(f)(o)|=\lim _{j \rightarrow \infty}\left|z\left(g_{j}\right)(o)\right| & =\lim _{j \rightarrow \infty}\left|h\left(\alpha_{j}\right)\right| \int_{E_{j}} d y \\
& =\lim _{j \rightarrow \infty} \frac{\left|h\left(\alpha_{j}\right)\right|}{2^{j}\left|\alpha_{j}\right|} \\
& =\limsup _{j \rightarrow \infty} \frac{\left|h\left(\alpha_{j}\right)\right|}{2^{j}\left|\alpha_{j}\right|} \\
& \geq 1 .
\end{aligned}
$$

It is a contradiction. Hence $h$ satisfies (1.3).
Next, we deal with simple functions
Lemma 4.6. Let $z: L_{c}^{1}\left(\mathbb{R}^{n}\right) \rightarrow C\left(\mathbb{R}^{n}\right)$ be a valuation. Suppose that there exists a continuous function $h$ on $\mathbb{R}$ satisfying (1.2) and (1.3) such that

$$
z\left(\alpha \mathbb{1}_{E}\right)(x)=h(\alpha) \int_{\mathbb{R}^{n}} \mathbb{1}_{E}(y) e^{-x \cdot y} d y
$$

for every $\alpha \in \mathbb{R}, x \in \mathbb{R}^{n}$ and bounded Borel set $E \subset \mathbb{R}^{n}$. Then

$$
z(g)=\int_{\mathbb{R}^{n}}(h \circ g)(y) e^{-x \cdot y} d y
$$

for every simple function $g \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$.
Proof. Let $g \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$ be a simple function. We can write $g=\sum_{i=1}^{m} \alpha_{i} \mathbb{1}_{E_{i}}$, where $E_{1}, \ldots, E_{m}$ are disjoint bounded Borel sets and $\alpha_{1}, \ldots, \alpha_{m} \in \mathbb{R}$. Hence

$$
\begin{equation*}
z(g)=z\left(\sum_{i=1}^{m} \alpha_{i} \mathbb{1}_{E_{i}}\right)=z\left(\left(\alpha_{1} \mathbb{1}_{E_{1}}\right) \vee \cdots \vee\left(\alpha_{m} \mathbb{1}_{E_{m}}\right)\right)=\sum_{i=1}^{m} z\left(\alpha_{i} \mathbb{1}_{E_{i}}\right) \tag{4.20}
\end{equation*}
$$

where the last equation is the inclusion-exclusion principle for valuations on the lattice $\left(L_{c}^{1}\left(\mathbb{R}^{n}\right), \vee, \wedge\right)$.

Since $h \circ g=\sum_{i=1}^{m} h\left(\alpha_{i}\right) \mathbb{1}_{E_{i}}$, by (4.20), we obtain

$$
\begin{aligned}
z(g)=\sum_{i=1}^{m} z\left(\alpha_{i} \mathbb{1}_{E_{i}}\right) & =\sum_{i=1}^{m} h\left(\alpha_{i}\right) \int_{\mathbb{R}^{n}} \mathbb{1}_{E_{i}}(y) e^{-x \cdot y} d y \\
& =\int_{\mathbb{R}^{n}} \sum_{i=1}^{m} h\left(\alpha_{i}\right) \mathbb{1}_{E_{i}}(y) e^{-x \cdot y} d y=\int_{\mathbb{R}^{n}}(h \circ g)(y) e^{-x \cdot y} d y .
\end{aligned}
$$

Finally, we are ready to prove Theorem 1.3.
Proof of Theorem 1.3. Theorem 3.1 shows that $f \mapsto \mathcal{L}(h \circ f)$ is a continuous, GL $(n)$ covariant and logarithmic translation covariant valuation. It remains to show the reverse statement.

For a nonnegative function $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$, there exists an increasing sequence of nonnegative simple functions $\left\{g_{k}\right\} \subset L_{c}^{1}\left(\mathbb{R}^{n}\right)$ such that $g_{k} \uparrow f$ pointwise. The monotone convergence theorem gives that $\left\|g_{k}-f\right\| \rightarrow 0$. Note that every function $f \in L_{c}^{1}\left(\mathbb{R}^{n}\right)$ can be written as $f=f_{+}-f_{-}$, where

$$
f_{+}=\left\{\begin{array}{ll}
f(x), & x \in\{f \geq 0\} \\
0, & x \in\{f<0\}
\end{array}, \quad f_{-}=\left\{\begin{array}{ll}
0, & x \in\{f \geq 0\} \\
-f(x), & x \in\{f<0\}
\end{array} .\right.\right.
$$

Hence the above statement gives that there exists a sequence of simple functions $\left\{g_{k}\right\} \subset$ $L_{c}^{1}\left(\mathbb{R}^{n}\right)$ such that $g_{k} \rightarrow f$ pointwise and $\left\|g_{k}-f\right\| \rightarrow 0$ by the triangle inequality. Moreover,
the increasing sequence $\left|g_{k}(x)\right| \uparrow|f(x)|$ for every $x \in \mathbb{R}^{n}$. Due to the continuity of $z$, Lemma 4.5 and Lemma 4.6, we have

$$
\begin{equation*}
z(f)(x)=\lim _{k \rightarrow \infty} z\left(g_{k}\right)(x)=\lim _{i \rightarrow \infty} \int_{\mathbb{R}^{n}}\left(h \circ g_{k}\right)(y) e^{-x \cdot y} d y \tag{4.21}
\end{equation*}
$$

where $h$ is a continuous function satisfying (1.2) and (1.3). Therefore,

$$
\left|h \circ g_{k}\right| \leq \gamma\left|g_{k}\right| \leq \gamma|f| .
$$

The dominated convergence theorem, the continuity of $h$, and (4.21) now yield

$$
\begin{aligned}
z(f) & =\lim _{i \rightarrow \infty} \int_{\mathbb{R}^{n}}\left(h \circ g_{k}\right)(y) e^{-x \cdot y} d y \\
& =\int_{\mathbb{R}^{n}}(h \circ f)(y) e^{-x \cdot y} d y \\
& =\mathcal{L}(h \circ f) .
\end{aligned}
$$
