1. Introduction

Projection bodies were introduced by Minkowski at the turn of the previous century and have since become a central notion in convex geometry. They arise naturally in a number of different areas such as functional analysis, stochastic geometry and geometric tomography, see e.g., [5, 9, 12, 19, 44, 49, 50]. The fundamental affine isoperimetric inequality for projection bodies is the Petty projection inequality [38]: Among all convex bodies of given volume, the ones whose polar projection bodies have maximal volume are precisely the ellipsoids. This inequality turned out to be far stronger than the classical isoperimetric inequality. Lutwak, Yang, and Zhang [30] (see also Campi and Gronchi [6]) established an important $L_p$ Petty projection inequality for the (symmetric) $L_p$ analogue of the projection operator. This extension is the geometric core of a sharp affine $L_p$ Sobolev inequality which is significantly stronger than the classical $L_p$ Sobolev inequality, see [32, 52]. Recent advances in valuation theory by Ludwig [21] revealed that the $L_p$ projection operator used in [30] is only one representative of an entire class of $L_p$ extensions of the classical projection operator. In this article we establish the $L_p$ Petty projection inequality for each member of the family of $L_p$ projection operators. It is shown that each of these new inequalities strengthens and implies the previously known $L_p$ Petty projection inequality. Moreover, the two strongest inequalities are identified. Similar results for the $L_p$ Busemann–Petty centroid inequality are also established.

The celebrated Blaschke–Santaló inequality is by far the best known affine isoperimetric inequality (see e.g., [9, 14, 42]): The product of the volumes of polar reciprocal convex bodies is maximized precisely by ellipsoids. Lutwak and Zhang [34] obtained an important $L_p$ version of the Blaschke–Santaló inequality. Their inequality includes as a limiting case the classical inequality for origin-symmetric convex bodies. For convex bodies which are not origin-symmetric this $L_p$ extension yields an inequality which is weaker than the Blaschke–Santaló inequality. As an application of our work, we establish the correct $L_p$ analog of the Blaschke–Santaló inequality, one that includes as a limiting case the classical inequality for all convex bodies.
For a convex body $K$ (i.e., a nonempty, compact convex subset of $\mathbb{R}^n$) denote by $h(K, x) = \max\{x \cdot y : y \in K\}$, for $x \in \mathbb{R}^n$, the support function of $K$. The projection body $\Pi K$ of $K$ is the convex body whose support function in the direction $u$ is equal to the $(n-1)$-dimensional volume of the projection of $K$ onto the hyperplane orthogonal to $u$. An important recent result by Ludwig [21] has demonstrated the special place of projection bodies in the affine theory of convex bodies: The projection operator was characterized as the unique Minkowski valuation which is contravariant with respect to nondegenerate linear transformations.

A function $\Phi$ defined on a subset $\mathcal{L}$ of the set of convex bodies $\mathcal{K}^n$ and taking values in an abelian semigroup is called a valuation if

$$\Phi(K \cup L) + \Phi(K \cap L) = \Phi K + \Phi L,$$

whenever $K, L, K \cap L, K \cup L \in \mathcal{L}$. The theory of real valued valuations lies at the core of geometry. They were the critical ingredient in Dehn’s solution of Hilbert’s third problem. For information on the classical theory of valuations, see [18] and [35]. For some of the more recent results, see [1–4, 19–24].

First results on convex body valued valuations were obtained by Schneider [41] in the 1970s, where the addition of convex bodies in (1) is Minkowski addition defined by $h(K + L, \cdot) = h(K, \cdot) + h(L, \cdot)$, see also [17, 43, 45]. In recent years the investigations of these Minkowski valuations gained momentum through a series of articles by Ludwig [19, 21]. She obtained complete classifications of Minkowski valuations compatible with nondegenerate linear transformations (see Section 3 for precise definitions).

Projection bodies are part of the classical Brunn–Minkowski theory which is the result of joining the notion of volume with the usual vector addition of convex sets. The books by Gardner [9], Gruber [14] and Schneider [42] form an excellent introduction to the subject. In a series of articles [27, 28], Lutwak showed that merging the notion of volume with the $L_p$ Minkowski addition of convex sets, introduced by Firey, leads to a Brunn–Minkowski theory for each $p \geq 1$. Since Lutwak’s seminal work, the topic has been the focus of intense study, see e.g., [7, 10, 11, 21, 24, 29–34, 40, 46–48].

For $p > 1$, Ludwig [21] introduced a two-parameter family of convex bodies,

$$c_1 \cdot \Pi_p^+ K +_{p} c_2 \cdot \Pi_p^- K,$$

and established the $L_p$ analogue of her classification of the projection operator: She showed that the convex bodies defined in (2) constitute all of the $L_p$ extensions of projection bodies. Here, $\mathcal{K}_o^n$ is the set of convex bodies which contain the origin in their interiors and $c_1, c_2 \geq 0$ (not both zero). The convex body defined by (2) is an $L_p$ Minkowski combination of the nonsymmetric $L_p$ projection bodies $\Pi_p^\pm K$ (see Sections 2 and 3 for definitions).

The (symmetric) $L_p$ projection body $\Pi_p K$ of $K \in \mathcal{K}_o^n$, first defined in [30], is

$$\Pi_p K = \frac{1}{2} \cdot \Pi_p^+ K +_{p} \frac{1}{2} \cdot \Pi_p^- K.$$

As our main result we extend the $L_p$ Petty projection inequality for $\Pi_p$ by Lutwak, Yang, and Zhang to the entire class (2) of $L_p$ projection bodies.

Let $K^* = \{x \in \mathbb{R}^n : x \cdot y \leq 1$ for all $y \in K\}$ denote the polar body of $K \in \mathcal{K}_o^n$. We use $V(K)$ to denote the volume of $K$ and we write $B$ for the Euclidean unit ball. If $\Phi : \mathcal{K}_o^n \rightarrow \mathcal{K}_o^n$, we use $\Phi^* K$ to denote $(\Phi K)^*$. 
Theorem 1. Let $K \in \mathcal{K}_n^p$ and $p > 1$. If $\Phi_p K$ is the convex body defined by
\[ \Phi_p K = c_1 \cdot \Pi_p^+ K + p \cdot \Pi_p^- K, \]
where $c_1, c_2 \geq 0$ are not both zero, then
\[ V(K)^{n/p-1}V(\Phi_p^* K) \leq V(B)^{n/p-1}V(\Phi_p^* B), \]
with equality if and only if $K$ is an ellipsoid centered at the origin.

The case $\Phi_p = \Pi_p$ of Theorem 1 is the $L_p$ Petty projection inequality by Lutwak, Yang, and Zhang.

The natural problem arises to determine for fixed $K \in \mathcal{K}_n^p$ the extreme values of $V(\Phi_p K)$ among all suitably normalized (e.g., satisfying $\Phi_p B = B$) $L_p$ projection bodies (2). Here, we will show that for $K \in \mathcal{K}_n^p$,
\[ V(\Pi_n^+ K) \leq V(\Phi_p K) \leq V(\Pi_n^+ K). \]
If $K$ is not origin-symmetric and $p$ is not an odd integer, these inequalities are strict unless $\Phi_p = \Pi_n$, or $\Phi_p = \Pi_n^+$, respectively. This shows that each of the new inequalities established in Theorem 1 strengthens and implies the previously known $L_p$ Petty projection inequality and that the nonsymmetric operators $\Pi_n^+$ (and their multiples) give rise to the strongest inequalities.

Centroid bodies (volume normalized moment bodies) are a classical notion from geometry which have attracted increased attention in recent years, see e.g., [9, 12, 25, 26, 30]. The moment body $MK$ of a convex body $K$ is the convex body defined by
\[ h(MK, u) = \int_K |u \cdot x| \, dx, \quad u \in S^{n-1}. \]
If $K$ has nonempty interior, then $\Gamma K = V(K)^{-1}MK$ is the centroid body of $K$.

Petty established the Petty projection inequality as a consequence of the Busemann–Petty centroid inequality [37]: Among all convex bodies of given volume, the ones whose centroid bodies have minimal volume are precisely the ellipsoids. Lutwak, Yang, and Zhang [30] (see also Campi and Gronchi [6]) established the $L_p$ version of the Busemann–Petty centroid inequality: For $p > 1$ and convex bodies $K$ containing the origin in their interiors,
\[ V(K)^{n/p-1}V(M_p K) \leq V(B)^{n/p}, \]
with equality if and only if $K$ is an ellipsoid centered at the origin. Here, $M_p K$ denotes the (symmetric) $L_p$ moment body, defined in [34] by
\[ M_p K = \frac{1}{2} \cdot M_p^+ K + p \cdot \frac{1}{2} \cdot M_p^- K, \]
where $M_p^\pm K$ are the nonsymmetric $L_p$ moment bodies (see Section 3). Since their introduction $L_p$ moment bodies have become the focus of intense study, see e.g., [6, 8, 12, 15, 16, 21, 30, 51] and the noted paper [36].

Ludwig [21] characterized moment bodies as the unique (non-trivial) homogeneous Minkowski valuations which intertwine volume preserving linear transformations. For $p > 1$, Ludwig [21] introduced and characterized the two-parameter family
\[ c_1 \cdot M_p^+ K + p \cdot c_2 \cdot M_p^- K, \quad K \in \mathcal{K}_n^p, \]
as all of the possible $L_p$ analogues of moment bodies.
Our $L_p$ Busemann–Petty centroid inequality for the entire class (4) of $L_p$ moment bodies is:

**Theorem 2.** Let $K \in \mathcal{K}^n_o$ and $p > 1$. If $\Psi_p K$ is the convex body defined by

$$\Psi_p K = c_1 \cdot M_p^+ K + c_2 \cdot M_p^- K,$$

where $c_1, c_2 \geq 0$ are not both zero, then

$$V(K)^{-n/p-1} V(\Psi_p K) \geq V(B)^{-n/p-1} V(\Psi_p B),$$

with equality if and only if $K$ is an ellipsoid centered at the origin.

In fact, in Section 6 a stronger version of Theorem 2, valid for all star bodies, will be established.

For $K \in \mathcal{K}^n_o$ and suitably normalized (e.g., satisfying $\Psi_p B = B$) $L_p$ moment bodies (4), we will show that

$$V(M_p^+ K) \geq V(\Psi_p K) \geq V(M_p^\pm K).$$

If $K$ is not origin-symmetric and $p$ is not an odd integer, these inequalities are strict unless $\Psi_p = M_p^+$, or $\Psi_p = M_p^\pm$, respectively. Consequently, each of the new inequalities established in Theorem 2 strengthens and implies inequality (3). Moreover, the nonsymmetric operators $M_p^\pm$ provide the strongest version of the $L_p$ Busemann–Petty centroid inequality.

Recall that for $K \in \mathcal{K}^n_o$ the Blaschke–Santaló inequality states

$$V(K)V(\mathcal{K}^s) \leq V(B)^2,$$

with equality if and only if $K$ is an ellipsoid. Here, $K^s = (K - s)^*$ is the polar body of $K$ with respect to the Santaló point $s$ of $K$, i.e., the unique point $s \in \text{int} K$ which minimizes $V((K - x)^*)$ among all translates $K - x$, for $x \in \text{int} K$. From Theorem 2, we obtain:

**Corollary.** If $\Psi_p$ is defined as in Theorem 2, then for $K \in \mathcal{K}^n_o$,

$$V(K)^{n/p+1} V(\Psi_p^s K) \leq V(B)^{n/p+1} V(\Psi_p^s B),$$

with equality if and only if $K$ is an ellipsoid centered at the origin.

Here, the case $\Psi_p = M_p^+$ was established by Lutwak and Zhang [34]. We remark that $M_p^+ K$ converges to $K$ as $p \to \infty$. Thus, as a limiting case we obtain for $\Psi_p = M_p^+$ the classical Blaschke–Santaló inequality.

### 2. Background Material

In the following we state the necessary background material. For quick reference, we collect basic properties of $L_p$ mixed and dual mixed volumes.

The setting for this article is Euclidean $n$-space $\mathbb{R}^n$ with $n \geq 3$. We will also assume throughout that $1 < p < \infty$. Thus, in the following we will omit these restrictions on $n$ and $p$.

Associated with a convex body $K \in \mathcal{K}^n_o$ is its surface area measure, $S(K, \cdot)$, on $S^{n-1}$. For a Borel set $\omega \subseteq S^{n-1}$, $S(K, \omega)$ is the $(n - 1)$-dimensional Hausdorff measure of the set of all boundary points of $K$ for which there exists a normal vector of $K$ belonging to $\omega$. By Minkowski’s uniqueness theorem (see e.g., [42, p. 397]), the convex body $K$ is determined up to translation by the measure $S(K, \cdot)$.
We call a convex body $K \in \mathcal{K}^n_0$ *smooth* if its boundary is $C^2$ with everywhere positive curvature. For a smooth convex body $K$, the surface area measure $S(K, \cdot)$ is absolutely continuous with respect to spherical Lebesgue measure:

$$dS(K, u) = f(K, u) \, du, \quad u \in S^{n-1}.$$  

The positive continuous function $f(K, \cdot)$ is called the *curvature function* of $K$. It is the reciprocal of the Gauss curvature as a function of the outer normals.

For $p \geq 1$, $K, L \in \mathcal{K}^n_0$ and $\alpha, \beta \geq 0$ (not both zero), the $L_p$ Minkowski combination $\alpha \cdot K + \beta \cdot L$ is the convex body defined by

$$h(\alpha \cdot K + \beta \cdot L, \cdot)^p = ah(K, \cdot)^p + \beta h(L, \cdot)^p.$$

Introduced by Firey in the 1960’s, this notion is the basis of what has become known as the $L_p$ Brunn–Minkowski theory (or the Brunn–Minkowski–Firey theory). Obviously, $L_p$ Minkowski and the usual scalar multiplications are related by $\alpha \cdot K = \alpha^{1/p} K$.

For $K, L \in \mathcal{K}^n_0$, the $L_p$ mixed volume, $V_p(K, L)$, was defined in [27] by

$$\frac{n}{p} V_p(K, L) = \lim_{\varepsilon \to 0^+} \frac{V(K + \varepsilon \cdot L) - V(K)}{\varepsilon}.$$  

Clearly, the diagonal form of $V_p$ reduces to ordinary volume, i.e., for $K \in \mathcal{K}^n_0$,

$$V_p(K, K) = V(K).$$

It was shown in [27] that corresponding to each convex body $K \in \mathcal{K}^n_0$, there is a positive Borel measure on $S^{n-1}$, the $L_p$ surface area measure $S_p(K, \cdot)$ of $K$, such that for every $L \in \mathcal{K}^n_0$,

$$V_p(K, L) = \frac{1}{n} \int_{S^{n-1}} h(L, u)^p dS_p(K, u).$$

The measure $S_1(K, \cdot)$ is just the surface area measure of $K$. Moreover, the $L_p$ surface area measure is absolutely continuous with respect to $S(K, \cdot)$:

$$dS_p(K, u) = h(K, u)^{1-p} dS(K, u), \quad u \in S^{n-1}.$$

It was shown in [27] that, if $K, L \in \mathcal{K}^n_0$ and $p \neq n$, then

$$S_p(K, \cdot) = S_p(L, \cdot) \implies K = L$$

and, if $p = n$, then

$$S_n(K, \cdot) = S_n(L, \cdot) \implies K = \lambda L, \quad \lambda > 0.$$  

These uniqueness properties of the $L_p$ surface area measure are consequences of the $L_p$ Minkowski inequality [27]: If $K, L \in \mathcal{K}^n_0$, then

$$V_p(K, L)^n \geq V(K)^{n-p} V(L)^p,$$

with equality if and only if $K$ and $L$ are dilates.

Firey’s $L_p$ Brunn–Minkowski inequality states: If $K, L \in \mathcal{K}^n_0$, then

$$V(K + p \cdot L)^{p/n} \geq V(K)^{p/n} + V(L)^{p/n},$$

with equality if and only if $K$ and $L$ are dilates.

For a compact set $L$ in $\mathbb{R}^n$ which is star-shaped with respect to the origin, we denote by $\rho(L, x) = \max\{\lambda \geq 0 : \lambda x \in L\}, \ x \in \mathbb{R}^n \setminus \{0\}$, the radial function of $L$. If $\rho(L, \cdot)$ is positive and continuous, we call $L$ a star body. The set of star bodies is denoted by $\mathcal{S}^n$. 
If $K \in K_n$ is a convex body, then it follows from the definitions of support functions and radial functions, and the definition of the polar body of $K$, that

$$
\rho(K^*, \cdot) = h(K, \cdot)^{-1} \quad \text{and} \quad h(K^*, \cdot) = \rho(K, \cdot)^{-1}.
$$

For $\alpha, \beta \geq 0$ (not both zero), the $L_p$ harmonic radial combination $\alpha \cdot K \tilde{\tau}_p + \beta \cdot L$ of $K, L \in S^n$ is the star body defined by

$$
\rho(\alpha \cdot K \tilde{\tau}_p + \beta \cdot L, \cdot)^{-p} = \alpha \rho(K, \cdot)^{-p} + \beta \rho(L, \cdot)^{-p}.
$$

Although our notation does not reflect the obvious difference between $L_p$ and dual $L_p$ scalar multiplication, there should be no possibility of confusion. Clearly, $L_p$ harmonic radial and the usual scalar multiplications are related by $\alpha \cdot K = \alpha^{-1/p} K$.

For convex bodies, Firey started investigations of harmonic $L_p$ combinations which were continued by Lutwak leading to a dual $L_p$ Brunn–Minkowski theory. The dual $L_p$ mixed volume $\tilde{V}_{-p}(K, L)$ of $K, L \in S^n$ was defined in [28] by

$$
-\frac{n}{p} \tilde{V}_{-p}(K, L) = \lim_{\varepsilon \to 0^+} \frac{V(K \tilde{\tau}_p \varepsilon \cdot L) - V(K)}{\varepsilon}.
$$

Clearly, the diagonal form of $\tilde{V}_{-p}$ reduces to ordinary volume, i.e., for $L \in S^n$,

$$
\tilde{V}_{-p}(L, L) = V(L).
$$

The polar coordinate formula for volume leads to the following integral representation of the dual $L_p$ mixed volume $\tilde{V}_{-p}(K, L)$ of the star bodies $K, L$:

$$
\tilde{V}_{-p}(K, L) = \frac{1}{n} \int_{S^{n-1}} \rho(K, u)^{n+p} \rho(L, u)^{-p} \, du.
$$

Here, integration is with respect to spherical Lebesgue measure. An application of Hölder’s integral inequality to (12) yields the dual $L_p$ Minkowski inequality [28]: If $K, L \in S^n$, then

$$
\tilde{V}_{-p}(K, L)^n \geq V(K)^{n+p} V(L)^{-p},
$$

with equality if and only if $K$ and $L$ are dilates.

The dual $L_p$ Brunn–Minkowski inequality [28] is: If $K, L \in S^n$, then

$$
V(K \tilde{\tau}_p L)^{-p/n} \geq V(K)^{-p/n} + V(L)^{-p/n},
$$

with equality if and only if $K$ and $L$ are dilates.

3. Nonsymmetric $L_p$ Projection and Moment Bodies

In this section we define nonsymmetric $L_p$ projection bodies $\Pi_p^+ K$ as well as nonsymmetric $L_p$ moment bodies $M_p^+ K$ and discuss basic properties of the corresponding operators.

Recall that the volume of the Euclidean unit ball $B$ is given by

$$
\kappa_n = \pi^{n/2}/\Gamma(1 + \frac{n}{2}).
$$

We define $c_{n,p}$ by

$$
c_{n,p} = \frac{\Gamma\left(\frac{n+p}{2}\right)}{\pi^{(n-1)/2} \Gamma\left(\frac{1+p}{2}\right)}.
$$
For each finite Borel measure $\mu$ on $S^{n-1}$, we define a continuous function $C_p^+\mu$ on $S^{n-1}$, the non-symmetric $L_p$ cosine transform of $\mu$, by

$$(C_p^+\mu)(u) = c_{n,p} \int_{S^{n-1}} (u \cdot v)^p \, d\mu(v), \quad u \in S^{n-1},$$

where $(u \cdot v)_+ = \max\{u \cdot v, 0\}$. For $f \in C(S^{n-1})$, let $C_p^+f$ be the non-symmetric $L_p$ cosine transform of the absolutely continuous measure (with respect to spherical Lebesgue measure) with density $f$. The normalization above was chosen so that $C_p^+1 = 1$.

The non-symmetric $L_p$ projection body $\Pi_p^+K$ of $K \in \mathcal{K}_n^0$, first considered in [28], is the convex body defined by

$$h(\Pi_p^+K, \cdot)^p = C_p^+S_p(K, \cdot).$$

For a star body $L \in S^n$, define the non-symmetric $L_p$ moment body of $L$ by

$$h(M_p^+L, \cdot)^p = C_p^+\rho(L, \cdot)^{n+p}.$$  

Using polar coordinates, it is easy to verify that for $L \in S^n$,

$$(15) \quad h(M_p^+L, u)^p = c_{n,p}(n+p) \int_L (u \cdot x)^p \, dx, \quad u \in S^{n-1}. $$

Note that the normalizations are chosen such that $M_p^+B = B$ and $\Pi_p^+B = B$. For $K \in \mathcal{K}_n^0$, we also define

$$M_p^-K = M_p^+(-K) \quad \text{and} \quad \Pi_p^-K = \Pi_p^+(-K).$$

For a finite measure $\mu$ on $S^{n-1}$, it is not hard to show that

$$\lim_{p \to 1^+} (C_p^+\mu)(u) = \frac{1}{2\kappa_{n-1}} \left\{ \int_{S^{n-1}} |u \cdot v| \, d\mu(v) + \int_{S^{n-1}} u \cdot v \, d\mu(v) \right\},$$

where the first integral is the spherical cosine transform $C\mu$ of $\mu$. Recall that pointwise convergence of support functions on $S^{n-1}$ implies convergence in the Hausdorff metric of the respective bodies (cf. [42, p. 54]). Thus, since $h(\Pi_K, \cdot) = \frac{1}{2}CS(K, \cdot)$ and since area measures have their center of mass at the origin, we obtain for every $K \in \mathcal{K}_n^0$ as $p \to 1$,

$$(16) \quad \Pi_p^+K \to \kappa_{n-1}^{-1}\Pi K \quad \text{and} \quad M_p^+K \to \frac{n+1}{2\kappa_{n-1}} (M(K) + m(K)).$$

Here, $m(K)$ is up to volume normalization the centroid of $K$:

$$m(K) = \int_K x \, dx.$$  

From representation (15), we obtain for $K \in \mathcal{K}_n^0$ as $p \to \infty$,

$$M_p^+K \to K.$$  

A map $\Phi$ defined on $\mathcal{K}^n$ and taking values in $\mathcal{K}^n$ is called $\text{SL}(n)$ covariant, if for all $K \in \mathcal{K}^n$ and every $\phi \in \text{SL}(n)$,

$$\Phi(\phi K) = \phi \Phi K.$$

It is said to be $\text{SL}(n)$ contravariant, if for all $K \in \mathcal{K}^n$ and every $\phi \in \text{SL}(n)$,

$$\Phi(\phi K) = \phi^{-T} \Phi K,$$

where $\phi^{-T}$ denotes the inverse of the transpose of $\phi$. 

PROOF COPY NOT FOR DISTRIBUTION
As usual, $\Phi$ is called \textit{homogeneous of degree} $r$, for $r \in \mathbb{R}$, if $\Phi(\lambda K) = \lambda^r \Phi(K)$ for all $K \in \mathcal{K}^n$ and every $\lambda > 0$. We say $\Phi$ is \textit{linearly associating} if $\Phi$ is $\text{SL}(n)$ co- or contravariant and homogeneous of degree $r$ for some $r \in \mathbb{R}$.

It was shown in \cite{Ludwig} that $\Pi^\pm_p$ is an $n/p - 1$ homogeneous and $\text{SL}(n)$ contravariant map, while $M^\pm_p$ is $\text{SL}(n)$ covariant and homogeneous of degree $n/p + 1$, i.e., for every $\phi \in \text{SL}(n)$ and every $\lambda > 0$,

$$\Pi^\pm_p(\phi K) = \phi^{-T} \Pi^\pm_p K \quad \text{and} \quad \Pi^\pm_p(\lambda K) = \lambda^{n/p - 1} \Pi^\pm_p K$$

for every $K \in \mathcal{K}^n_0$ and

$$M^\pm_p(\phi K) = \phi M^\pm_p K \quad \text{and} \quad M^\pm_p(\lambda K) = \lambda^{n/p + 1} M^\pm_p K.$$

A map $\Phi : \mathcal{K}^n_0 \to \mathcal{K}^n_0$ is called an $L_p$ \textit{Minkowski valuation} if

$$\Phi(K \cup L) +_p \Phi(K \cap L) = \Phi K +_p \Phi L,$$

whenever $K, L, K \cup L \in \mathcal{K}^n_0$. The \textit{trivial} $L_p$ Minkowski valuations are $L_p$ Minkowski combinations of the identity and central reflection. In \cite{Ludwig} Ludwig has shown that $L_p$ combinations of $\Pi^\pm_p$ and $M^\pm_p$ are the (essentially) uniquely determined linearly associating $L_p$ Minkowski valuations. In order to state her result, let $\mathcal{P}^\alpha_0$ ($\mathcal{P}^\alpha$) denote the set of polytopes in $\mathbb{R}^n$ which contain the origin (in their interior). For $n \geq 3$, Ludwig \cite{Ludwig} proved the following:

\textbf{Theorem 3.1.} If $\Phi : \mathcal{P}^\alpha_0 \to \mathcal{K}^n_0$ is a \textit{non-trivial} $L_p$ Minkowski valuation which is \textit{linearly associating}, then there exist constants $c_0 \in \mathbb{R}$ and $c_1, c_2 \geq 0$ such that for every $K \in \mathcal{P}^\alpha_0$,

$$\Phi K = \begin{cases} c_1 \Pi_p K & \text{if } p = 1 \\ c_1 \cdot \Pi^+_p K +_p c_2 \cdot \Pi^-_p K & \text{if } p > 1 \end{cases}$$

or

$$\Phi K = \begin{cases} c_0 m(K) + c_1 MK & \text{if } p = 1 \\ c_1 \cdot M^+_p K +_p c_2 \cdot M^-_p K & \text{if } p > 1. \end{cases}$$

Theorem 3.1 and (16) show that the $L_p$ combinations of $\Pi^\pm_p$ and $M^\pm_p$ are all $L_p$ extensions of projection and moment bodies.

Ludwig’s classification results in \cite{Ludwig} were in fact formulated with a different parametrization of the families $c_1 \cdot \Pi^+_p +_p c_2 \cdot \Pi^-_p$ and $c_1 \cdot M^+_p +_p c_2 \cdot M^-_p$. These alternative representations will be very useful for us as well: For $\tau \in [-1, 1]$, define the function $\varphi_\tau : \mathbb{R} \to [0, \infty)$ by

$$\varphi_\tau(t) = |t| + \tau t,$$

and, for $K \in \mathcal{K}^n_0$, let $\Pi^\alpha_p K \in \mathcal{K}^n_0$ be the convex body with support function

$$h(\Pi^\alpha_p K, u)^p = c_{n,p}(\tau) \int_{S^{n-1}} \varphi_\tau(u \cdot v)^p dS_p(K, v), \quad u \in S^{n-1},$$

where

$$c_{n,p}(\tau) = \frac{c_{n,p}}{(1 + \tau)^p + (1 - \tau)^p}.$$

The normalization is again chosen such that $\Pi^\alpha_0 B = B$ for every $\tau \in [-1, 1]$. From the definition of $\Pi^\pm_p$ it is easy to verify that

$$\Pi^\pm_p K = \frac{(1 + \tau)^p}{(1 + \tau)^p + (1 - \tau)^p} \cdot \Pi^+_p K +_p \frac{(1 - \tau)^p}{(1 + \tau)^p + (1 - \tau)^p} \cdot \Pi^-_p K.$$
In particular, if $K \in \mathcal{K}_o^n$ is origin-symmetric, then for any $\tau, \sigma \in [-1, 1]$, we have $\Pi_{\tau}^+ K = \Pi_{\sigma}^+ K$.

By (18), the one-parameter family $\Pi_{\tau}^+$ constitutes a bridge between the $L_p$ projection body operator $\Pi_p$ (the case $\tau = 0$) as introduced by Lutwak, Yang, and Zhang and their non-symmetric analogues $\Pi_{\tau}^\pm$ ($\tau = \pm 1$). From (18), it also follows that for every pair $c_1, c_2 \geq 0$ (not both zero) there exist a $\tau \in [-1, 1]$ and a constant $c > 0$ such that

$$c_1 \cdot \Pi_{\tau}^+ K + c_2 \cdot \Pi_{\tau}^- K = c \Pi_{\tau}^+ K.$$  

Thus, instead of working with the $L_p$ combinations of the operators $\Pi_{\tau}^\pm$ we can consider multiples of the operators $\Pi_{\tau}^\pm$, $\tau \in [-1, 1]$.

For a star body $L \in S^n$, let $\tilde{M}_{\tau}^+ L \in \mathcal{K}_o^n$ be the convex body defined by

$$h(\tilde{M}_{\tau}^+ L, u)^p = c_{n,p}(\tau) \int_{S^{n-1}} \varphi_\tau(u \cdot v)^p \rho(L, v)^{n+p} \, dv, \quad u \in S^{n-1}.$$  

Then $\tilde{M}_{\tau}^+ B = B$ for every $\tau \in [-1, 1]$ and

$$\tilde{M}_{\tau}^+ L = \frac{(1 + \tau)^p}{(1 + \tau)^p + (1 - \tau)^p} \cdot \tilde{M}_{\tau}^+ L + \frac{(1 - \tau)^p}{(1 + \tau)^p + (1 - \tau)^p} \cdot \tilde{M}_{\tau}^- L.$$  

In particular, if $L \in S^n$ is origin-symmetric, then for any $\tau, \sigma \in [-1, 1]$, we have $\tilde{M}_{\tau}^+ L = \tilde{M}_{\sigma}^+ L$.

The family $\tilde{M}_{\tau}^+$ forms a link between $L_p$ moment bodies (the case $\tau = 0$) as introduced by Lutwak and Zhang and their non-symmetric analogues ($\tau = \pm 1$). From (21), it follows that for every pair $c_1, c_2 \geq 0$ (not both zero) there exists a $\tau \in [-1, 1]$ and a constant $c > 0$ such that

$$c_1 \cdot \tilde{M}_{\tau}^+ K + c_2 \cdot \tilde{M}_{\tau}^- K = c \tilde{M}_{\tau}^+ K.$$  

Thus, instead considering $L_p$ combinations of $\tilde{M}_{\tau}^\pm$ we can work with multiples of $\tilde{M}_{\tau}^+$, $\tau \in [-1, 1]$.

The following simple lemma will be crucial. Here and in the following, $\Pi_{\tau}^* K$ denotes the polar body of $\Pi_{\tau}^+ K$.

**Lemma 3.2.** If $K \in \mathcal{K}_o^n$ and $L \in S^n$, then

$$V_p(K, \tilde{M}_{\tau}^+ L) = \tilde{V}_p(L, \Pi_{\tau}^* K).$$  

**Proof.** If $K \in \mathcal{K}_o^n$ and $L \in S^n$, then, by (6) and definition (20),

$$V_p(K, \tilde{M}_{\tau}^+ L) = \frac{c_{n,p}(\tau)}{n} \int_{S^{n-1}} \int_{S^{n-1}} \varphi_\tau(u \cdot v) \rho(L, v)^{n+p} \, dv \, dS_p(K, u).$$  

Thus, by Fubini’s theorem, (10) and definition (17),

$$V_p(K, \tilde{M}_{\tau}^+ L) = \frac{1}{n} \int_{S^{n-1}} \rho(L, v)^{n+p} \rho(\Pi_{\tau}^* K, v)^{-p} \, dv = \tilde{V}_p(L, \Pi_{\tau}^* K).$$  

q.e.d.

In the following we discuss injectivity properties of the operators $\Pi_{\tau}^+$ and $\tilde{M}_{\tau}^+$. To this end, we first collect some basic facts about spherical harmonics (see e.g., Schneider [42, Appendix]). We use $\mathcal{H}_o^k$ to denote the finite dimensional vector space of spherical harmonics of dimension $n$ and order $k$. Let $N(n, k)$ denote the dimension of $\mathcal{H}_o^k$. 

PROOF COPY NOT FOR DISTRIBUTION
Let $L_2(S^{n-1})$ denote the Hilbert space of square integrable functions on $S^{n-1}$ with its usual inner product $(\cdot, \cdot)$. The spaces $H_{n,k}$ are pairwise orthogonal with respect to this inner product. In each space $H_{n,k}$ we choose an orthonormal basis $\{Y_{k1}, \ldots, Y_{kN(n,k)}(n,k)\}$. Then $\{Y_{k1}, \ldots, Y_{kN(n,k)} : k \in \mathbb{N}\}$ forms a complete orthogonal system in $L_2(S^{n-1})$, i.e., for every $f \in L_2(S^{n-1})$, the Fourier series

$$f \sim \sum_{k=0}^{\infty} \pi_k f$$

converges in quadratic mean to $f$, where $\pi_k f$ is the orthogonal projection of $f$ onto $H_{n,k}$:

$$\pi_k f = \sum_{i=1}^{N(n,k)} (f, Y_{ki}) Y_{ki}.$$ 

In particular, for $f \in C(S^n)$,

$$\pi_k f = 0 \quad \text{for all } k \in \mathbb{N} \implies f = 0.$$ 

Thus, $f \in C(S^{n-1})$ is uniquely determined by its series expansion.

For a finite Borel measure $\mu$ on $S^{n-1}$, we define

$$\pi_k \mu = \sum_{i=1}^{N(n,k)} \int_{S^{n-1}} Y_{ki}(u) \, d\mu(u) \, Y_{ki}.$$ 

If $f \in C(S^{n-1})$, then

$$(f, \pi_k \mu) = \int_{S^{n-1}} (\pi_k f)(u) \, d\mu(u).$$

Thus, by (23), the measure $\mu$ is uniquely determined by its (formal) series expansion:

$$\pi_k \mu = 0 \quad \text{for all } k \in \mathbb{N} \implies \mu = 0.$$ 

Of particular importance for us is the Funk–Hecke theorem: Let $\phi$ be a continuous function on $[-1, 1]$. If $T_\phi$ is the transformation on the set of finite Borel measures on $S^{n-1}$ defined by

$$(T_\phi \mu)(u) = \int_{S^{n-1}} \phi(u \cdot v) \, d\mu(v),$$

then there are real numbers $a_k[T_\phi]$, the multipliers of $T_\phi$, such that

$$T_\phi Y_k = a_k[T_\phi] Y_k$$

for every spherical harmonic $Y_k \in H_{n,k}^\phi$. In particular, by Fubini’s theorem

$$\pi_k (T_\phi \mu) = a_k[T_\phi] \pi_k \mu.$$ 

We call a transformation $T$ defined on the space of finite Borel measures on $S^{n-1}$ and satisfying (25) a multiplier transformation. Using (24) and (25), it follows that a multiplier transformation $T_\phi$ is injective if and only if all multipliers $a_k[T_\phi]$ are non-zero.

By the Funk–Hecke theorem, the nonsymmetric $L_p$ cosine transform $C_p^{\|}$ is a multiplier transformation. The numbers $a_k[C_p^{\|}]$ have been calculated in [39], see also [15]: If $p$ is not an integer, then

$$a_k[C_p^{\|}] \neq 0,$$ 

PROOF COPY NOT FOR DISTRIBUTION
and if \( p \in \mathbb{N} \), then
\[
(27) \quad a_k[C^+_p] = 0 \text{ if and only if } k = 2 + p, 4 + p, 6 + p, \ldots
\]

Consequently, \( C^+_p \) is injective if and only if \( p \) is not an integer.

Since a convex body \( K \in \mathcal{K}_n^o \) is uniquely determined by its support function, by its radial function and by its \( L^p \) surface area measure, we conclude that the operators \( \Pi^+_p \) and \( M^+_p \) are injective if and only if \( p \) is not an integer. It is easy to verify that
\[
\Pi^+_p K = (-\Pi^+_p K) \quad \text{and} \quad M^+_p K = (-\Pi^+_p K) = -M^+_p K.
\]

Thus, the injectivity properties of \( \Pi^+_p \) and \( M^+_p \) carry over to \( \Pi^-_p \) and \( M^-_p \).

We will frequently use the following consequence of (26) and (27).

**Lemma 3.3.** If \( K \in \mathcal{K}_n^o, L \in \mathbb{S}^n \) and \( p \) is not an odd integer, then
\[
\Pi^+_p K = \Pi^-_p K \quad \text{or} \quad M^+_p L = M^-_p L
\]
holds if and only if \( K \), respectively \( L \), is origin-symmetric.

**Proof.** From the definition of \( \Pi^-_p \) and \( M^-_p \), it follows that \( \Pi^+_p K = \Pi^-_p K \) and \( M^+_p L = M^-_p L \) for origin-symmetric bodies \( K \) and \( L \).

Conversely, assume that \( \Pi^+_p K = \Pi^-_p K \). Then \( \Pi^+_p K \) is origin-symmetric, i.e., \( h(\Pi^+_p K, \cdot)^p \) is even. Note that \( f \in C(S^{n-1}) \) (or a measure \( \mu \) on \( S^{n-1} \)) is even if and only if \( \pi_k f = 0 \) (or \( \pi_k \mu = 0 \), respectively) for every odd \( k \in \mathbb{N} \).

Since \( C^+_p \) is a multiplier transformation, we obtain from (26) and (27) that \( S_p(K, \cdot) \) is even. Thus, by the uniqueness property of \( S_p(K, \cdot) \), the body \( K \) must be origin-symmetric.

The case \( M^+_p L = M^-_p L \) is similar, using \( \rho(L, \cdot)^{n+p} \) instead of \( S_p(K, \cdot) \).

q.e.d.

### 4. Class reduction

A standard method for establishing geometric inequalities is to prove them first for a dense class of bodies (e.g., polytopes or smooth bodies) and then, by taking the limit, the inequality is obtained for all bodies. This approach has the major disadvantage that critical equality conditions are usually lost for the limiting case. In order to prove affine isoperimetric inequalities along with their equality conditions for all convex bodies, it is often sufficient to establish the inequalities only for a very small class of bodies, e.g., the class of \( L^p \) moment bodies. This class reduction technique was introduced by Lutwak [25] and further applied in [30] and [34].

The crucial result in this section, Lemma 4.2, shows that in order to establish Theorem 1, we need only prove it for the class of smooth convex bodies (in fact the much smaller class of \( L^p \) moment bodies will suffice). The tools to derive this fact are provided by Lemma 3.2 and the following lemma.

**Lemma 4.1.** If \( K \in \mathcal{K}_n^o \), then the convex body \( M^+_p K \) is smooth.

**Proof.** In order to show that \( M^+_p K \) is smooth, we need to prove that its support function \( h := h(M^+_p K, \cdot) \) is of class \( C^2 \) and that the convex body \( M^+_p K \) has everywhere positive radii of curvature (see [42, p. 111]). To this end, we...
first assume that $\tau = 1$, i.e., $h = h(M^+_p K, \cdot)$. Let $f$ be a continuous function on $\mathbb{R}^n$ and let $u \in \mathbb{R}^n \setminus \{0\}$. A simple calculation shows that

$$
\frac{\partial}{\partial u_i} \int_K (u \cdot x)^p f(x) \, dx = p \int_K (u \cdot x)^{p-1} x_i f(x) \, dx.
$$

Thus, the function $h$ is of class $C^2$ if $\tau = 1$. Let $(h_{ij})_{i,j=1}^{n-1}$ denote the Hessian matrix of $h$ at $u$ with respect to an orthonormal basis $\{e_1, \ldots, e_n\}$ of $\mathbb{R}^n$ with $e_n = u$. By [42, Corollary 2.5.3], the convex body $M^+_p K$ has everywhere positive radii of curvature if and only if

$$
\det(h_{ij})_{i,j=1}^{n-1} > 0.
$$

Using (28), we obtain for $h_{ij}(u)$ up to some positive constant

$$
\int_K (x \cdot u)^p \, dx \int_K (x \cdot u)^{p-2} (x \cdot b_i)(x \cdot b_j) \, dx
$$

$$
= \int_K (x \cdot u)^{p-1} (x \cdot b_i) \, dx \int_K (x \cdot u)^{p-1} (x \cdot b_j) \, dx.
$$

An application of Hölder’s inequality shows that $(h_{ij})_{i,j=1}^{n-1}$ is positive definite and thus, in particular, $\det(h_{ij}(u))_{i,j=1}^{n-1} > 0$. Hence, $M^+_p K$ is smooth and, since $M^-_p K = -M^+_p K$, we also obtain that $M^-_p K$ is smooth. For $\tau \in (-1, 1)$, the assertion follows from a similar (but more tedious) calculation, by using (21) and (28).

The crucial result of this section is contained in the following lemma which reduces the proof of Theorem 1 to the class of smooth convex bodies.

**Lemma 4.2.** In order to prove Theorem 1, it is sufficient to verify the following assertion: If $K \in \mathcal{K}^n_\circ$ is smooth, then for every $\tau \in [-1, 1]$, $V(K)^{n/p-1} V(\Pi_p^\tau K) \leq V(B)^{n/p}$, with equality if and only if $K$ is an ellipsoid centered at the origin.

**Proof.** For $K \in \mathcal{K}^n_\circ$, let $\Phi_p K = c_1 \cdot \Pi^+_p K + c_2 \cdot \Pi^-_p K$, where $c_1, c_2 \geq 0$ are not both zero. By (19), there exist a $\tau \in [-1, 1]$ and a constant $c > 0$ such that $\Phi_p K = c \Pi_p^\tau K$. Since $\Pi_p^\tau B = B$, we conclude, that the assertion of Theorem 1 is equivalent to the following statement: If $K \in \mathcal{K}^n_\circ$, then for every $\tau \in [-1, 1]$,

$$
V(K)^{n/p-1} V(\Pi_p^\tau K) \leq V(B)^{n/p},
$$

with equality if and only if $K$ is an ellipsoid centered at the origin.

It remains to show that inequality (29) along with its equality conditions holds if and only if it holds for smooth bodies. To this end, we will prove that, for $K \in \mathcal{K}^n_\circ$,

$$
V(K)^{n/p-1} V(\Pi_p^\tau K) \leq V(M^+_p \Pi_p^\tau K)^{n/p-1} V(\Pi_p^\tau M^+_p \Pi_p^\tau K),
$$

with equality if and only if $K$ and $M^+_p \Pi_p^\tau K$ are dilates. Thus, by Lemma 4.1, any convex body at which $V(K)^{n/p-1} V(\Pi_p^\tau K)$ attains a maximum must be smooth.

In order to see (30), take $L = \Pi_p^\tau K$ in Lemma 3.2 and use (11) to conclude

$$
V(\Pi_p^\tau K) = V_p(K, M^+_p \Pi_p^\tau K).
$$

**Proof copy not for distribution.**
Thus, by the $L_p$ Minkowski inequality (8), we obtain
\begin{equation}
V(\Pi_p^* K)^n \geq V(K)^{n-p} V(M_p^{\tau} \Pi_p^* K)^p,
\end{equation}
with equality if and only if $K$ and $M_p^{\tau} \Pi_p^* K$ are dilates. Conversely, replace $K$ by $M_p^{\tau} L$, for some star body $L$, in Lemma 3.2 and use (5) to obtain
\begin{equation}
V(M_p^{\tau} L) = \tilde{V}_p(L, \Pi_p^* M_p^{\tau} L).
\end{equation}
Thus, the dual $L_p$ Minkowski inequality (13) yields
\begin{equation}
V(M_p^{\tau} L)^n \geq V(L)^{n+p} V(\Pi_p^* M_p^{\tau} L)^{-p},
\end{equation}
with equality if and only if $L$ and $\Pi_p^* M_p^{\tau} L$ are dilates.

Now take $L = \Pi_p^* K$ in (32) to get
\begin{equation}
V(\Pi_p^* \Pi_p^* K)^n \geq V(\Pi_p^* K)^{n+p} V(\Pi_p^* M_p^{\tau} \Pi_p^* K)^{-p},
\end{equation}
with equality if and only if $\Pi_p^* K$ and $\Pi_p^* M_p^{\tau} \Pi_p^* K$ are dilates.

A combination of inequalities (31) and (33) finally yields (30) and finishes the proof. q.e.d.

By (16), the case $p = 1$ of inequality (29) reduces to the classical Petty projection inequality. Since we do not wish to reprove this classical inequality, we note again that we restrict our attention to the case $1 < p < \infty$.

In Section 6, we will again use the class reduction technique to show that Theorem 2 follows from Theorem 1.

5. Steiner Symmetrization and $\Pi_p^*$

In this section we establish the important fact that Steiner symmetrization intertwines with the operator $\Pi_p^*$ for every $\tau \in [-1, 1]$. This was proved in [30] for the case $\tau = 0$. For arbitrary $\tau \in [-1, 1]$, the proof is similar but certain modifications are needed to settle the equality conditions in Theorem 1.

In the following let $\{e_1, \ldots, e_n\}$ be an orthonormal basis of $\mathbb{R}^n$. We will frequently use the decomposition $\mathbb{R}^n = \mathbb{R}^{n-1} \times \mathbb{R}$, where we assume that $e_n^\perp = \mathbb{R}^{n-1}$. Clearly, for every convex body $K \in K_o^n$ there exist functions $\overline{z}, \overline{\pi} : K[e_n^\perp] \to \mathbb{R}$ such that $K$ can be represented in the form
\begin{equation}
K = \{ (x, t) \in \mathbb{R}^{n-1} \times \mathbb{R} : \overline{z}(x) \leq t \leq \overline{\pi}(x), x \in K[e_n^\perp] \}.
\end{equation}
Note that the number $\overline{\pi} - \overline{z}$ is the length of the chord of $K$ through $x$ parallel to $e_n$. It is easy to verify that $\overline{z}$ is convex and that $\overline{\pi}$ is a concave function. Thus, $\overline{z}$ and $\overline{\pi}$ are continuous on $K_o := \text{relint} K[e_n^\perp]$. If $K$ is smooth, then $\overline{z}$ and $\overline{\pi}$ are $C^1$ functions on $K_o$.

Let $D \subseteq \mathbb{R}^{n-1}$ be an open convex set which contains the origin in its interior. For a $C^1$ function $z : D \to \mathbb{R}$ define
\begin{equation}
\langle z \rangle(x) = z(x) - x \cdot \nabla z(x), \quad x \in D.
\end{equation}
Note that the operator $\langle \cdot \rangle$ is linear. Moreover, the kernel of $\langle \cdot \rangle$ consists only of linear functions:
\begin{equation}
\langle z \rangle(x) = 0 \quad \text{for all } x \in D \quad \implies \quad z \text{ is linear on } D.
\end{equation}

The following auxiliary result can be found in [30, Lemma 11].
Lemma 5.1. If $K \in \mathcal{K}_n$ is a smooth convex body given by

$$K = \{(x,t) \in \mathbb{R}^n \times \mathbb{R} : \underline{z}(x) \leq t \leq \overline{z}(x), \ x \in K|e_n^+\},$$

then for every $x \in \text{relint} \ K|e_n^+$,

$$h(K, (\nabla \underline{z}(x), -1)) = (-\underline{z})(x) \quad \text{and} \quad h(K, (-\nabla \overline{z}(x), 1)) = (\overline{z})(x).$$

Recall that for smooth $K \in \mathcal{K}_n$, the surface area measure $S(K, \cdot)$ and thus, by (7), also the $L_p$ surface area measure $S_p(K, \cdot)$ are absolutely continuous with respect to spherical Lebesgue measure:

$$dS_p(K, u) = h(K, u)^{1-p}f(K, u) du, \quad u \in S^{n-1}.$$ 

Here $f(K, \cdot)$ is the curvature function of the smooth convex body $K$.

For smooth $K \in \mathcal{K}_n$, the spherical image map $\nu : \text{bd} K \to S^{n-1}$ is defined by letting $\nu(x)$, for $x \in \text{bd} K$, be the unique outer unit normal vector of $K$ at $x$. By [42, p. 112], for any integrable function $g$ on $S^{n-1}$ we have

$$\int_{S^{n-1}} g(u)f(K, u) du = \int_{\text{bd} K} g(\nu(x)) d\mathcal{H}^{n-1}(x),$$

where $\mathcal{H}^{n-1}$ denotes $(n-1)$-dimensional Hausdorff measure. Thus, by (17) and (36), we obtain the following representation of $\Pi^x_pK$, $\tau \in [-1, 1]$:

$$h(\Pi^x_pK, u)^p = c_{n,p}(\tau) \int_{\text{bd} K} \varphi_{\tau}(u \cdot \nu(x))^p h(K, \nu(x))^{1-p} d\mathcal{H}^{n-1}(x).$$

If the smooth convex body $K$ is given by (34), then for any continuous function $h$ on $S^{n-1}$,

$$\int_{\text{bd} K} h(\nu(x)) d\mathcal{H}^{n-1}(x)$$

$$= \int_{K_0} h(\nu(x, \underline{z}(x))) \sqrt{1 + \left\|\nabla \underline{z}(x)\right\|^2} + h(\nu(x, \overline{z}(x))) \sqrt{1 + \left\|\nabla \overline{z}(x)\right\|^2} dx.$$

Recall that $K_0 = \text{relint} \ K|e_n^+$. Since for any $x \in K_0$,

$$\nu(x, \underline{z}(x)) = \frac{(\nabla \underline{z}(x), -1)}{\sqrt{1 + \left\|\nabla \underline{z}(x)\right\|^2}} \quad \text{and} \quad \nu(x, \overline{z}(x)) = \frac{(-\nabla \overline{z}(x), 1)}{\sqrt{1 + \left\|\nabla \overline{z}(x)\right\|^2}},$$

we obtain from Lemma 5.1, (37), and the homogeneity of $h(K, \cdot)$ and $\varphi_{\tau}$:

Lemma 5.2. If $K \in \mathcal{K}_n$ is a smooth convex body given by

$$K = \{(x,t) \in \mathbb{R}^{n-1} \times \mathbb{R} : \underline{z}(x) \leq t \leq \overline{z}(x), \ x \in K|e_n^+\},$$

then for every $(y,t) \in \mathbb{R}^{n-1} \times \mathbb{R}$,

$$c_{n,p}^{-1}(\tau)h(\Pi^x_pK, (y, t))^p$$

$$= \int_{K_0} \varphi_{\tau}(t - y \cdot \nabla \overline{z}(x))^p(\overline{z})(x)^{1-p} + \varphi_{\tau}(y \cdot \nabla \underline{z}(x) - t)^p(-\underline{z})(x)^{1-p} dx.$$
Lemma 5.3. If $K \in \mathcal{K}_n^0$ is smooth, then for every $u \in S^{n-1}$,
\[ S_u \Pi_p^* K \subseteq \Pi_p^* S_u K. \]

If equality holds in the above inclusion, there exists an $r \in [0,1]$ such that the points which divide the (directed) chords of $K$ parallel to $u$ in the proportion $r : 1 - r$ are coplanar.

Proof. Since $\Pi_p^*$ is linearly associating, we can assume without loss of generality that $u = e_n$. Let the convex body $K$ be given by
\[ K = \{ (x,t) \in \mathbb{R}^{n-1} \times \mathbb{R} : \xi(x) \leq t \leq \Xi(x), \ x \in K|e_n^\perp \}. \]

The definition of Steiner symmetrization and (10) show that
\[ S_{e_n} \Pi_p^* K \subseteq \Pi_p^* S_{e_n} K \]
holds if and only if
\[ h(\Pi_p^* K, (y,s)) = h(\Pi_p^* K, (y,t)) = 1 \quad \text{with} \ s \neq t \]
implies
\[ h(\Pi_p^* S_{e_n} K, (y, \frac{1}{2}s - \frac{1}{2}t)) \leq 1. \]

Let $(y,s), (y,t) \in \mathbb{R}^{n-1} \times \mathbb{R}$ with $s \neq t$ and suppose that
\[ h(\Pi_p^* K, (y,s)) = h(\Pi_p^* K, (y,t)) = 1. \]

Note that the Steiner symmetral of a smooth convex body is again smooth. Since the triangle inequality implies
\[ \varphi_r \left( \frac{1}{2}(s-t) - y \cdot \frac{1}{2}\nabla(\xi - \Xi)(x) \right) \leq \frac{1}{2} \left( \varphi_r(s - y \cdot \nabla \xi(x)) + \varphi_r(y \cdot \nabla \Xi(x) - t) \right) \]
and
\[ \varphi_r(y \cdot \frac{1}{2}\nabla(\Xi - \xi)(x) - \frac{1}{2}(s-t)) \leq \frac{1}{2} \left( \varphi_r(y \cdot \nabla \Xi(x) - s) + \varphi_r(t - y \cdot \nabla \xi(x)) \right), \]
we obtain from Lemma 5.2 and the linearity of the operator $\langle \cdot \rangle$,
\[ c_n^{-1}(\tau) h(\Pi_p^* S_{e_n} K, (y, \frac{1}{2}s - \frac{1}{2}t))^p \]
\[ = \int_{K_n} \varphi_r \left( \frac{1}{2}(s-t) - y \cdot \frac{1}{2}\nabla(\xi - \Xi)(x) \right) \langle \frac{1}{2}(\xi - \Xi) \rangle \langle x \rangle^{1-p} dx \]
\[ + \int_{K_n} \varphi_r(y \cdot \frac{1}{2}\nabla(\Xi - \xi)(x) - \frac{1}{2}(s-t)) \langle \frac{1}{2}(\xi - \Xi) \rangle \langle x \rangle^{1-p} dx \]
\[ \leq \frac{1}{2} \int_{K_n} \left( \varphi_r(s - y \cdot \nabla \xi(x)) + \varphi_r(y \cdot \nabla \Xi(x) - t) \right) \langle \xi - \Xi \rangle \langle x \rangle^{1-p} dx \]
\[ + \frac{1}{2} \int_{K_n} \left( \varphi_r(y \cdot \nabla \Xi(x) - s) + \varphi_r(t - y \cdot \nabla \xi(x)) \right) \langle \xi - \Xi \rangle \langle x \rangle^{1-p} dx. \]

By the convexity of the function $t \mapsto t^p$, it follows that for real numbers $a, b \geq 0$ and $c, d > 0$,
\[ (a + b)^p(c + d)^{1-p} \leq a^p c^{1-p} + b^p d^{1-p}, \]

Proof Copy Not for Distribution
with equality if and only if \(ad = bc\), see [30, Lemma 8]. Since \(K \in \mathcal{K}_n^c\), Lemma 5.1 implies that \(\langle \tau \rangle(x), \langle -\tau \rangle(x) > 0\) for every \(x \in K_o\). Thus, we obtain the desired inequality

\[
c_{n,p}^{-1}(\tau) h(\Pi_p^c S_{c_n} K, (y, \frac{1}{2} s - \frac{1}{2} t))^p \\
\leq \frac{1}{2} \int_{K_o} \varphi_\tau(s - y \cdot \nabla \tau(x))^{p\langle \tau \rangle(x)^{1-p}} + \varphi_\tau(y \cdot \nabla \tau(x) - s)^{p\langle -\tau \rangle(x)^{1-p}} dx \\
+ \frac{1}{2} \int_{K_o} \varphi_\tau(t - y \cdot \nabla \tau(x))^{p\langle \tau \rangle(x)^{1-p}} + \varphi_\tau(y \cdot \nabla \tau(x) - t)^{p\langle -\tau \rangle(x)^{1-p}} dx \\
= \frac{1}{2} c_{n,p}^{-1}(\tau) h(\Pi_p^c K, (y, s))^p + \frac{1}{2} c_{n,p}^{-1}(\tau) h(\Pi_p^c K, (y, t))^p = c_{n,p}^{-1}(\tau).
\]

If there is equality in (38), then \(h(\Pi_p^c K, (y, s)) = h(\Pi_p^c K, (y, t)) = 1\) with \(s \neq t\) implies \(h(\Pi_p^c S_{c_n} K, (y, \frac{1}{2} s - \frac{1}{2} t)) = 1\). Consequently, equality must hold in the above chain of inequalities. The equality conditions of (39) now yield for every \(x \in K_o\),

\[
\varphi_\tau(s - y \cdot \nabla \tau(x))^{\langle \tau \rangle(x)} = \varphi_\tau(y \cdot \nabla \tau(x) - t)^{\langle \tau \rangle(x)},
\]

\[
\varphi_\tau(y \cdot \nabla \tau(x) - s)^{\langle \tau \rangle(x)} = \varphi_\tau(t - y \cdot \nabla \tau(x))^{\langle -\tau \rangle(x)}.
\]

Hence, for \(y = 0\), we conclude that

\[
\langle |s| + \tau s \rangle^{\langle \tau \rangle(x)} = \langle |t| - \tau t \rangle^{\langle \tau \rangle(x)},
\]

\[
\langle |s| - \tau s \rangle^{\langle \tau \rangle(x)} = \langle |t| + \tau t \rangle^{\langle -\tau \rangle(x)}.
\]

Since \((0, s), (0, t) \in \text{bd } \Pi_p^c K\), there must exist a constant \(c > 0\) such that \(\langle \tau + c \tau \rangle = 0\). Thus, by (35), \(\tau + c \tau\) has to be linear. Define \(r := c/(c + 1)\).

Since \(\tau + c \tau\) is linear, the points which divide the (directed) chords of \(K\) parallel to \(c_n\) in the proportion \(r : r - 1\) are coplanar.

### 6. Proof of the main theorems

We are now in a position to establish our main results. We first complete the proof of Theorem 1. Then we show that the nonsymmetric \(L_p\) projection bodies lead to the strongest affine isoperimetric inequality among the family of inequalities established in Theorem 1. The corresponding result for nonsymmetric \(L_p\) moment bodies will be given after the proof of Theorem 2. We emphasize again that we are assuming throughout that \(n \geq 3\) and \(1 < p < \infty\).

In order to settle the equality conditions of Theorem 1, we will need the following generalization of the Bertrand–Brunn theorem due to Gruber [13]:

**Theorem 6.1.** Let \(K \in \mathcal{K}_n^c\) be a convex body. Suppose that for any family of parallel chords of \(K\) there exists an \(r \in [0, 1]\) such that the points which divide the (directed) chords of \(K\) in the proportion \(r : r - 1\) are coplanar. Then \(K\) is an ellipsoid.

By Lemma 4.2, the following result completes the proof of Theorem 1:

**Theorem 6.2.** If \(K \in \mathcal{K}_n^c\) is smooth, then for every \(\tau \in [-1, 1]\),

\[
V(K)^{n/p-1}V(\Pi_p^c K) \leq V(B)^{n/p},
\]

with equality if and only if \(K\) is an ellipsoid centered at the origin.
Proof. Since Steiner symmetrization does not affect volume, we deduce from Lemma 5.3 that for every direction $u$,

$$V(K)^{n/p}V(\Pi_p^* K) \leq V(S_u K)^{n/p}V(\Pi_p^* S_u K).$$

If equality holds, there exists an $r \in [0,1]$ such that the points which divide the chords of $K$ parallel to $u$ in the proportion $r:1-r$ are coplanar.

We can now choose a sequence of Steiner symmetrals of the convex body $K$ which converges to $(V(K)/\kappa_n)^{1/n}B$ (see e.g., [14, p. 172]). By the continuity and the homogeneity of $\Pi_p^*$, we obtain

$$V(K)^{n/p}V(\Pi_p^* K) \leq V(B)^{n/p}.$$

If equality holds, then for every direction $u$ there exists an $r \in [0,1]$ such that the points which divide the chords of $K$ parallel to $u$ in the proportion $r:1-r$ are contained in a subspace of codimension 1 (by the proof of Lemma 5.3).

Together with Theorem 6.1, this implies that $K$ must be an ellipsoid centered at the origin.

q.e.d.

If $K \in K^o_n$ is origin-symmetric, then for any $\tau, \sigma \in [-1,1]$, $\Pi_p^* K = \Pi_p^\sigma K$ and Theorem 1 reduces to the $L_p$ Petty projection inequality established in [30]. If $K$ is not origin-symmetric, the following theorem shows that the nonsymmetric operators $\Pi_p^\sigma$ provide the strongest inequalities:

**Theorem 6.3.** For every $K \in K^o_n$,

$$V(\Pi_p^* K) \leq V(\Pi_p^\tau* K) \leq V(\Pi_p^{\pm}\tau K).$$

If $K$ is not origin-symmetric and $p$ is not an odd integer, there is equality in the left inequality if and only if $\tau = 0$ and equality in the right inequality if and only if $\tau = \pm 1$.

Proof. We may assume that $K$ is not origin-symmetric and that $p$ is not an odd integer (otherwise the statement is trivial or follows by approximation). Let $-1 < \tau < 1$. From (10) and the definition of $\Pi_p^\tau$, we obtain

$$\Pi_p^\tau K = \frac{(1+\tau)^p}{(1+\tau)^p + (1-\tau)^p} \cdot \Pi_p^{+\tau} K + \frac{(1-\tau)^p}{(1+\tau)^p + (1-\tau)^p} \cdot \Pi_p^{-\tau} K.\tag{40}$$

Here, multiplication is the dual $L_p$ scalar multiplication, i.e., $\lambda \cdot K = \lambda^{-1/p} K$.

Using the dual $L_p$ Brunn–Minkowski inequality (14), we obtain

$$V(\Pi_p^{\tau} K) \leq V(\Pi_p^{\pm\tau} K),\tag{41}$$

with equality if and only if $\Pi_p^{+\tau} K$ and $\Pi_p^{-\tau} K$ are dilates which is only possible if $\Pi_p^{+} K = \Pi_p^{-} K$. From Lemma 3.3, it follows that inequality (41) is strict for every $\tau \in (-1,1)$ which completes the proof of the right inequality.

In order to see the left inequality, note that the polar coordinate formula for volume yields

$$V(\Pi_p^{\tau} K) = \frac{1}{n} \int_{S^{n-1}} \rho(\Pi_p^{\tau} K, u)^n du.$$

Thus, using (40), we obtain

$$\frac{\partial}{\partial \tau} V(\Pi_p^{\tau} K) = f(\tau) \int_{S^{n-1}} \rho(\Pi_p^{\tau} K, u)^{n+p} \left( \rho(\Pi_p^{+} K, u)^{-p} - \rho(\Pi_p^{-} K, u)^{-p} \right) du,$$

where $f(\tau)$ is the function defined in (10).

Proof Copy Not for Distribution
where
\[(42) \quad f(\tau) = -\frac{2(1-\tau)^{p-1}(1+\tau)^{p-1}}{(1+\tau)^p + (1-\tau)^p} < 0.\]
The continuous function \(\tau \mapsto V(\Pi_p^+K)\) must attain a minimum on \([-1,1]\). By the first part of the proof, the points where this minimum is attained, are contained in \((-1,1)\). If \(\bar{\tau}\) is such a point, then
\[
\frac{\partial}{\partial \tau} V(\Pi_p^+K) \bigg|_{\tau=\bar{\tau}} = 0.
\]
By the calculation above and definition (12), this is equivalent to
\[(43) \quad \tilde{V}_{-p}(\Pi_p^+\Pi_p^+K) = \tilde{V}_{-p}(\Pi_p^+K, \Pi_p^+K).\]
Since, for \(Q, K, L \in S^n\) and \(\alpha, \beta \geq 0\),
\[\tilde{V}_{-p}(Q, \alpha \cdot K, \tilde{\beta} \cdot L) = \alpha \tilde{V}_{-p}(Q, K) + \beta \tilde{V}_{-p}(Q, L),\]
the representation (40) and the identity (43) imply
\[\tilde{V}_{-p}(\Pi_p^+\Pi_p^+K) = \tilde{V}_{-p}(\Pi_p^+K, \Pi_p^+(-K)).\]
By (11) and since \(\Pi_p^+\Pi_p^+(-K) = -\Pi_p^+K\), we therefore obtain
\[V(\Pi_p^+K) = \tilde{V}_{-p}(\Pi_p^+K, -\Pi_p^+K).\]
Using the dual \(L_p\) Minkowski inequality (13), we conclude that \(\Pi_p^+K\) is origin-symmetric. By (40), this is equivalent to
\[((1+\tau)^p - (1-\tau)^p) \rho(\Pi_p^+K, u)^{-p} - \rho(\Pi_p^+K, u)^{-p} = 0\]
for every \(u \in S^{n-1}\). As before, an application of Lemma 3.3, shows that \(\Pi_p^+K \neq \Pi_p^+\Pi_p^+K\). Thus, we must have \(\bar{\tau} = 0\) which proves the left inequality.

In view of (22), our next result is a stronger version of Theorem 2:

**Theorem 6.4.** If \(L \in S^n\), then for every \(\tau \in [-1,1]\),
\[V(L)^{n/p}V(M_p^+L) \geq V(B)^{-n/p},\]
with equality if and only if \(L\) is an ellipsoid centered at the origin.

**Proof.** By definition, \(M_p^+L \in K_0^p\). In Theorem 1, take \(K = M_p^+L\), to obtain
\[(44) \quad V(\Pi_p^+M_p^+L)^{-p} \geq V(B)^{-n/p}V(M_p^+L)^{-n/p},\]
with equality if and only if \(M_p^+L\) is an ellipsoid centered at the origin. Combine this with (32) and get
\[V(L)^{-n/p}V(M_p^+L) \geq V(B)^{-n/p}V(M_p^+L)^{-n/p}.\]
If equality holds in this inequality, then equality must hold in (32) and (44). Consequently, \(L\) and \(\Pi_p^+M_p^+L\) are dilates and \(M_p^+L\) is an ellipsoid centered at the origin. Since \(\Pi_p^+\) is linearly associating, this implies that \(L\) is an ellipsoid centered at the origin.

Now a combination of Theorem 2 with the Blaschke–Santaló inequality yields the Corollary stated in the introduction.
Our final result shows that the strongest inequalities in Theorem 6.4 are provided by the nonsymmetric operators $M^\pm$:

**Theorem 6.5.** For every $L \in S^n$, 
\[ V(M_p L) \geq V(M^+_p L) \geq V(M^\pm_p L), \]
If $L$ is not origin-symmetric and $p$ is not an odd integer, there is equality in the left inequality if and only if $M^+ L = \lambda$ and equality in the right inequality if and only if $\lambda = \pm 1$.

**Proof.** We may again assume that $L$ is not origin-symmetric and $p$ is not an odd integer. Let $-1 < \tau < 1$. Using that for $L_p$ scalar multiplication $\lambda \cdot K = \lambda^{1/p} K$, an application of the $L_p$ Brunn–Minkowski inequality (9) to the representation (21) yields
\[ V(M^p_{1/L} L) \geq V(M^p_{1/L} L), \]
with equality if and only if $M^+_p L$ and $M^-_p L$ are dilates which is only possible if $M^+_p L = M^-_p L$. From Lemma 3.3, it follows that inequality (45) is strict for every $\tau \in (-1,1)$ which completes the proof of the right inequality.

In order to prove the left inequality, we have to calculate the derivative of the function $\tau \mapsto V(M^p_{1/L} L)$ with respect to $\tau$: For fixed $\tilde{\tau} \in (-1,1)$, note that
\[ \frac{V(M^p_{1/L} L) - V_1(M^p_{1/L} L, M^p_{1/L} L)}{\tau - \tilde{\tau}} = \frac{1}{n} \int_{S^{n-1}} h(M^p_{1/L} L, u) - h(M^p_{1/L} L, u) \frac{dS(M^p_{1/L} L, u)}{\tau - \tilde{\tau}}, \]
and
\[ \frac{V_1(M^p_{1/L} L, M^p_{1/L} L) - V(M^p_{1/L} L)}{\tau - \tilde{\tau}} = \frac{1}{n} \int_{S^{n-1}} h(M^p_{1/L} L, u) - h(M^p_{1/L} L, u) \frac{dS(M^p_{1/L} L, u)}{\tau - \tilde{\tau}}. \]
From the uniform convergence of support functions and the weak convergence of surface area measures, we deduce that the limits
\[ \lim_{\tau \to \tau^1} \frac{V(M^p_{1/L} L) - V_1(M^p_{1/L} L, M^p_{1/L} L)}{\tau - \tilde{\tau}}, \quad \lim_{\tau \to \tau^2} \frac{V_1(M^p_{1/L} L, M^p_{1/L} L) - V(M^p_{1/L} L)}{\tau - \tilde{\tau}} \]
exist and are both equal to
\[ g(\tilde{\tau}) := \frac{1}{n} \int_{S^{n-1}} \left. \frac{\partial}{\partial \tau} h(M^p_{1/L} L, u) \right|_{\tau} dS(M^p_{1/L} L, u). \]
Using the $L_p$ Minkowski inequality (8) for $p = 1$ in (46), shows that
\[ g(\tilde{\tau}) \leq V(M^p_{1/L} L)^{(n-1)/n} \liminf_{\tau \to \tau^1} \frac{V(M^p_{1/L} L)^{1/n} - V(M^p_{1/L} L)^{1/n}}{\tau - \tilde{\tau}} \]
and
\[ g(\tilde{\tau}) \geq V(M^p_{1/L} L)^{(n-1)/n} \limsup_{\tau \to \tau^1} \frac{V(M^p_{1/L} L)^{1/n} - V(M^p_{1/L} L)^{1/n}}{\tau - \tilde{\tau}}. \]
Thus, we obtain
\[ g(\tilde{\tau}) = V(M^p_{1/L} L)^{(n-1)/n} \lim_{\tau \to \tau} \frac{V(M^p_{1/L} L)^{1/n} - V(M^p_{1/L} L)^{1/n}}{\tau - \tilde{\tau}}. \]
In particular, the function \( \tau \mapsto V(M_p^\tau L)^{1/n} \) is differentiable at \( \bar{\tau} \). The definition of \( g(\bar{\tau}) \) yields

\[
\frac{\partial}{\partial \tau} V(M_p^\tau L) = \int_{S^{n-1}} \frac{\partial}{\partial \tau} h(M_p^\tau L, u) \, dS(M_p^\tau L, u).
\]

Using (21), we obtain for this derivative

\[
-f(\tau) \int_{S^{n-1}} h(M_p^\tau L, u)^{1-p} \left( h(M_p^\tau L, u)^p - h(M_p^{-\tau} L, u)^p \right) \, dS(M_p^\tau L, u),
\]

where \( f(\tau) \) is given by (42).

The continuous function \( \tau \mapsto V(M_p^\tau L) \) must attain a maximum on \([-1, 1]\). By the first part of the proof, the points where this maximum is attained, are contained in \((-1, 1)\). If \( \bar{\tau} \) is such a point, then

\[
\left. \frac{\partial}{\partial \tau} V(M_p^\tau L) \right|_{\tau = \bar{\tau}} = 0.
\]

By the calculation above and definition (6), this is equivalent to

\[
V_p^+ (M_p^\tau L, M_p^\tau L) = V_p^+ (M_p^\tau L, M_p^{-\tau} L).
\]

Since, for \( Q, K, L \in K^n_0 \) and \( \alpha, \beta > 0 \),

\[
V_p(Q, \alpha \cdot K + \beta \cdot L) = \alpha V_p(Q, K) + \beta V_p(Q, L),
\]

the representation (21) and the identity (47) imply

\[
V_p^+ (M_p^\tau L, M_p^\tau L) = V_p^+ (M_p^\tau L, M_p^\tau(-L)).
\]

By (5) and since \( M_p^\tau(-L) = -M_p^\tau L \), we therefore obtain

\[
V(M_p^\tau L) = V_p(M_p^\tau L, -M_p^\tau L).
\]

Using the \( L_p \) Minkowski inequality (8), we conclude that \( M_p^\tau L \) is origin-symmetric. By (21), this is equivalent to

\[
\left( (1 + \bar{\tau})^p - (1 - \bar{\tau})^p \right) \left( h(M_p^\tau L, u)^p - h(M_p^{-\tau} L, u)^p \right) = 0
\]

for every \( u \in S^{n-1} \). By Lemma 3.3, \( M_p^\tau L \neq M_p^{-\tau} L \). Thus, we must have \( \bar{\tau} = 0 \) which proves the left inequality.
