Summary

Łukasiewicz functions on $[0, 1]$

Definition (Fuzzy operations on $[0, 1]$)

conjunction: $x \wedge y := \min(x, y)$

disjunction: $x \vee y := \max(x, y)$

negation: $\neg x := 1 - x$

weak disjunction: $x + y := \min(x + y, 1)$

strong conjunction: $x \& y := \max(x + y - 1, 0) = \neg(\neg x + \neg y)$

implication: $x \rightarrow y := (\neg x) + y = \max\{z : (x \& z) \leq y\}$

Note: $x \vee y = (x \rightarrow y) \rightarrow y$, $\neg x = (x \rightarrow 0)$, ...

Note: In this talk, fuzzy = Łukasiewicz = Ł.

Propositional Łukasiewicz logic

Syntax:

- ▶ propositional variables p_1, p_2, \dots
- ▶ connectives: $+, \&, \vee, \wedge, \neg, \rightarrow, \top, \perp$
- ▶ formulas: $p_1 \& p_1 \rightarrow p_2, \dots$

Semantics:

- ▶ Assignments: $b : \{p_1, p_2, \dots\} \rightarrow [0, 1]$
- ▶ Truth function $\bar{b} : \text{Formulas} \rightarrow [0, 1]$:
 $\bar{b}(p) = b(p), \bar{b}(\top) = 1, \bar{b}(\varphi \& \psi) = \bar{b}(\varphi) \& \bar{b}(\psi), \dots$

Ł-Tautologies: $\{\varphi : \forall b (\bar{b}(\varphi) = 1)\}$

Warning: $p_1 \vee \neg p_1$ is not a tautology.

Łukasiewicz predicate logic

Syntax:

- ▶ Language \mathcal{L} : Relation symbols R, \dots, S (with arities)
- ▶ Object variables x, y, \dots
- ▶ connectives, quantifiers: \wedge, \forall, \dots
- ▶ formulas: e.g. $\forall x \exists y (R(x, y) \wedge R(y, y) \rightarrow S(y, x))$.

Łukasiewicz predicate logic 2

Semantics:

- ▶ \mathcal{L} -structure $\mathcal{M} = (M, R^{\mathcal{M}}, \dots, S^{\mathcal{M}})$:
 $R^{\mathcal{M}} : M^k \rightarrow [0, 1], \dots, S^{\mathcal{M}} : M^m \rightarrow [0, 1]$.
- ▶ Assignment $v : \{x, y, \dots\} \rightarrow M$
- ▶ Fuzzy values of formulas: $\|\varphi\|_v^{\mathcal{M}}$.
 - ▶ $\|R(x, y)\|_v^{\mathcal{M}} := R^{\mathcal{M}}(v(x), v(y))$
 - ▶ $\|\forall x \varphi(x)\| := \inf\{\|\varphi\|_{v_{x \mapsto m}}^{\mathcal{M}} : m \in M\}$
 - ▶ etc.
- ▶ $\|\varphi\| := \inf\{\|\varphi\|^{\mathcal{M}} : \mathcal{M} \text{ an } \mathcal{L}\text{-structure}\}$.

Ł-validities: $\{\varphi : \varphi \text{ closed}, \|\varphi\|^{\mathcal{M}} = 1 \text{ for every } \mathcal{M}\}$.

Proof ingredients

Summary

Complexity - propositional

Classical propositional logic on $\{0, 1\}$

The set $\{\varphi : \forall b (\bar{b}(\varphi) = 1)\}$ of classical (or “crisp”) tautologies is

- ▶ decidable;
 - ▶ **co-NP-complete**. [folklore?]
-

Propositional **Ł**-logic on $[0, 1]$:

The set $\{\varphi : \forall b (\bar{b}(\varphi) = 1)\}$ of Ł-Tautologies is

- ▶ decidable;
- ▶ **co-NP-complete**. [same proof]

Complexity - first order

Classical first order predicate logic on $\{0, 1\}$:

The set $\{\varphi : \mathcal{M} \models \varphi \text{ for all crisp } \mathcal{M}\}$ of classical validities is

- ▶ not decidable
- ▶ computably enumerable (c.e., Σ_1^0)
- ▶ in fact: Σ_1^0 -complete.

First order \mathbb{L} -logic on $[0, 1]$:

The set $\{\varphi : \|\varphi\|^{\mathcal{M}} = 1 \text{ for all fuzzy } \mathcal{M}\}$ of \mathbb{L} -validities is

- ▶ not decidable, not Σ_1^0 , not even Σ_2^0 (Scarpellini)
- ▶ Π_2^0 (Novak-Pavelka)
- ▶ Π_2^0 -complete (Ragaz; G^*)

Summary

arithmetical hierarchy: formulas

First order language of arithmetic: $+, \cdot, \leq, =, 0, 1$.

Abbreviation: $\vec{x} = (x_1, \dots, x_n)$, $\vec{y} = (y_1, \dots, y_k)$.

- ▶ Σ_1^0 -formulas: $\exists x_1 \psi(x_1, \vec{y})$, where ψ is quantifier-free (or: only bounded quantifiers: $\forall u < v, \exists u < v$.)
- ▶ Π_1^0 -formulas: $\forall x_1 \psi$, or $\neg(\Sigma_1^0)$.
- ▶ Σ_n^0 -formulas: $\exists x_1 \forall x_2 \cdots \exists x_n \psi(\vec{x}, \vec{y})$

Remark

Most arithmetical formulas that appear in practice are Σ_n^0 , for small n . ($n = 1, 2, 3$.)

Example: “there are infinitely many twin primes”:

$$\forall x \exists p (p > x, p \text{ prime}, p + 2 \text{ prime}).$$

arithmetical hierarchy: sets

A subset of \mathbb{N}^k is Σ_n^0 iff it can be defined by a Σ_n^0 -formula.

- ▶ The Σ_1^0 sets are exactly the c.e. (r.e.) sets, or **semi-decidable** sets. (projections of decidable sets in \mathbb{N}^{k+1})
- ▶ The **decidable** sets are exactly the sets which are both Σ_1^0 and Π_1^0 .
- ▶ $\Sigma_1^0 \subsetneq \Sigma_2^0 \subsetneq \dots$, similarly $\Pi_1^0 \subsetneq \Pi_2^0 \subsetneq \dots$.
- ▶ If C is Π_n^0 , and f is computable, then $f^{-1}(C)$ is also Π_n^0 .
- ▶ C is a **complete Π_n^0 -set**, if C is Π_n^0 , and every Π_n^0 -set B can be **reduced to C** , i.e., is of the form $f^{-1}(C)$, for some computable f .

(These are the sets which are maximally complicated among the Π_n^0 sets, similar to co-NP-complete)

Examples of ...-complete sets

- ▶ The set of all (codes for) Turing machines that halt on input 0 is Σ_1^0 complete.
- ▶ The set of all (codes for) programs that describe a function with infinite domain is Π_2^0 -complete.
- ▶ The set $Th_n(\mathbb{N})$ of all (codes for) true Σ_n^0 -formulas is Σ_n^0 -complete.

Definition

The set $Th(\mathbb{N})$ (also called **true arithmetic**) is defined as the set of all (codes for) true sentences: $Th(\mathbb{N}) = \bigcup_{n=1}^{\infty} Th_n(\mathbb{N})$.

$Th(\mathbb{N})$ is “infinitely more” complicated than any $Th_n(\mathbb{N})$.

Summary

Computable structures

Definition

A crisp structure $\mathcal{M} = (M, R^{\mathcal{M}}, \dots, S^{\mathcal{M}})$ is “computable”, if

- ▶ M is a decidable subset of \mathbb{N} ,
- ▶ for each relation symbol R , the set $R^{\mathcal{M}}$ is a decidable subset of the respective \mathbb{N}^k .

A fuzzy structure $\mathcal{M} = (M, R^{\mathcal{M}}, \dots, S^{\mathcal{M}})$ is “computable”, if

- ▶ M is a decidable subset of \mathbb{N} ,
- ▶ for each relation symbol R the sets $\{(\vec{m}, q) : R^{\mathcal{M}}(\vec{m}) < q\}$ and $\{(\vec{m}, q) : R^{\mathcal{M}}(\vec{m}) \leq q\}$ are decidable subsets of the respective $\mathbb{N}^k \times \mathbb{Q}$.

Computationally valid sentences

Recall

- ▶ φ is classically valid, if $\mathcal{M} \models \varphi$ for all crisp structures \mathcal{M} ;
- ▶ φ is \mathbb{L} -valid, if $\|\varphi\|^{\mathcal{M}} = 1$, for all fuzzy structures \mathcal{M} .

Definition

φ is **C**-valid, if $\mathcal{M} \models \varphi$ for all **computable** crisp structures \mathcal{M} .

φ is **C**- \mathbb{L} -valid, if $\mathcal{M} \models \varphi$ for all **computable** fuzzy structures \mathcal{M} .

Theorem

1. *The set of C-validities is as complicated as $Th(\mathbb{N})$ (true arithmetic).*
2. *The set of C- \mathbb{L} -validities is as complicated as $Th(\mathbb{N})$.*

Summary

Tennenbaum's theorem

While any set of sentences (true in \mathbb{N}) has uncountably many (pairwise nonisomorphic) countable models, we have:

Theorem (Tennenbaum 1959)

*There is a single sentences σ such that \mathbb{N} is the unique **computable** model satisfying σ .*

Corollary

1. *$Th(\mathbb{N})$ can be computed from the set of C -validities.*
2. *$Th(\mathbb{N})$ can be computed from the set of C - \perp -validities.*

Part (1) is well-known and follows easily from Tennenbaum's 1959 theorem. The proof of part (2) is similar.

From fuzzy to crisp via rounding

Fix a language \mathcal{L} with finitely many relation symbols R, \dots, S .

- ▶ $\varepsilon_R := \exists x_1 \dots \exists x_k (R(\vec{x}) \wedge \neg R(\vec{x}))$ for k -ary R
- ▶ $\varepsilon_{\mathcal{L}} := \varepsilon_R \vee \dots \vee \varepsilon_S$ (disjunction over all relation symbols)

Let $\mathcal{M} = (M, R^{\mathcal{M}}, \dots, S^{\mathcal{M}})$ be a fuzzy \mathcal{L} -structure.

Define a crisp structure $\bar{\mathcal{M}}$ and a number $e^{\mathcal{M}} \in [0, \frac{1}{2}]$ as follows:

- ▶ The universe \bar{M} is the same as the universe of \mathcal{M} : $\bar{M} := M$.
- ▶ For each k -ary relation symbol R :
For all $\vec{a} \in M^k$: $\bar{\mathcal{M}} \models R(\vec{a})$ iff: $\|R(\vec{a})\|^{\mathcal{M}} > \frac{1}{2}$
- ▶ $e^{\mathcal{M}} := \|\varepsilon_{\mathcal{L}}\|^{\mathcal{M}}$.

Note: $e^{\mathcal{M}} = 0$ iff \mathcal{M} is crisp. Try to avoid the case $e^{\mathcal{M}} = \frac{1}{2}$.
